<sup>66</sup> C. Steigerwald and R. Zell, German P. 535,348, 1930, to I. G. Farbenind. A.-G.; *Chem. Abs.*, 1932, 26, 479.

Besides ultraviolet light and the per- compounds mentioned above, other polymerizing agents have been suggested. Taylor<sup>66</sup> subjected a mixture of vinyl acetate and mercury vapors to the resonance radiation of that metal. Young and Douglas<sup>67</sup> added about 2 per cent of lead tetraethyl to vinyl acetate, vinyl chloride, or a blend of the two, and heated the solution for 24 hours in an autoclave at 100°C. Also, a small proportion of acid acts as a catalyst, about 0.5 per cent of hydrochloric acid being sufficient, and the color of the polymer is not adversely affected as when a large quantity of acid is used.<sup>68</sup>

Vinyl esters may be stabilized against polymerization by storage over copper or copper compounds.<sup>69</sup> Sulphur also prevents the esters from forming resins, and only a trace is necessary for this purpose.<sup>69</sup> Such inhibitors are particularly useful if vinyl esters are to be exposed to sunlight.

### COATINGS

Polyvinyl acetate and chloroacetate were early suggested as bases for lacquers, using as solvents, esters, chlorinated hydrocarbons,<sup>70</sup> ketones, aldehydes and nitrohydrocarbons.<sup>71</sup> Since polymerization takes place before the film is formed, there is not as much change with age as is noted with coatings containing drying oils.<sup>72</sup> Other important features of these resins which promote their utilization are light color, flexibility, stability towards light and transparency to ultraviolet rays, and solubility in a wide range of solvents.<sup>73</sup>

Polyvinyl acetate dissolves or swells in polar organic liquids and in some other liquids of a very high dielectric constant.<sup>74</sup> It shows the following behavior in various organic liquids: Hydrocarbons: Insoluble in petroleum hydrocarbons but slowly dissolves in amylene; dissolves in benzene, toluene and xylene, with diminishing readiness. Esters: in general, lower members of a homologous series are better solvents than the higher ones; dissolves very rapidly in methyl and ethyl formates; rapidly, but not quite as fast in methyl and ethyl acetates, less rapidly in  $\beta$ -chloroethyl acetate, ethyl butyrate, benzoate and oxalate; dissolves slowly in butyl oxalate; insoluble in tricresyl phosphate, isoamyl phthalate, ethyl oleate. Ketones: Rapidly dissolves in acetone, less rapidly in methyl ethyl ketone and still less so in ethyl phenyl ketone. Alcohols: Soluble in methyl and ethyl alcohols, swells without dispersing in butyl and amyl alcohols, does not swell in hexyl and heptyl alcohols. Ethers: Swells but does not dissolve in ethyl ether, does not swell in n-butyl ether, dissolves in anisole and, less rapidly, in benzyl ethyl ether, dibenzyl ether and saffrole. Acetals: Methylal is a rapid solvent, but acetal produces only slight swelling. Acids: Dissolves readily in acetic and propionic acids, more slowly in butyric and still more slowly in lactic; insoluble in oleic acid. Aldehydes: Acetaldehyde, propionaldehyde, n-butyraldehyde and valeraldehyde are

fairly effective, but benzaldehyde, heptaldehyde, cinnamaldehyde and paraldehyde act very slowly. Halogenated hydrocarbons: Dissolves easily in chloroform and bromoform, less rapidly in propyl chloride and ethyl iodide. Miscellaneous: Dissolves in nitrobenzene and aniline; rapidly in acetonitrile and nitromethane; does not swell in formamide. 1,4-Dioxane<sup>72</sup> is a good solvent.

Colored lacquers are formed by adding dyes, such as water-insoluble amino- or polyamino-anthraquinone dyestuffs, which give colors that are fast to light.<sup>73</sup> The clear, colored products may be used on electric light bulbs.<sup>74</sup> Light-fast enamels contain ultramarine blue, ochre, lampblack or bronze powders.<sup>75</sup> A poly-

vinyl acetate solution mixed with red lead is suggested as an anti-rust paint.<sup>76</sup> Better adhesion is obtained with lacquers which are a mixture of polymers of different viscosity characteristics, as for example, high- and low-viscosity polyvinyl acetate or acetate of high viscosity and butyrate of low viscosity.<sup>77</sup> When employed as an undercoat for nitrocellulose lacquers, only a thin film should be applied, as otherwise the top coat tends to crack. A surface coating to render cellophane moisture-proof contains a vinyl polymer with about 1/3 part of paraffin wax and 1/2 part of plasticizer.<sup>78</sup> The solution is applied to sheets of regenerated cellulose and dried by baking.

Polyvinyl acetate is compatible with cellulose nitrate<sup>82</sup> and the methyl, ethyl and benzyl ethers of cellulose, but is not compatible with cellulose acetate. Polyvinyl chloroacetate is compatible only with cellulose ethers. Haehnel and Herrmann<sup>83</sup> found that the addition of polymerized vinyl acetate to nitrocellulose lacquers improves their gloss and adhesion. Flexible lacquers of this type are recommended as coatings for leather.<sup>84</sup> Polyvinyl acetate may be used with cellulose acetate if another synthetic resin compatible with the two is present. Resins for this purpose are those from sulphonamides and formaldehyde, diphenylolpropane and formaldehyde, phenol and furfural, acetone or aniline and furfural, and the resin made by heating lactic acid. Moss<sup>85</sup> made a lacquer by dissolving 100 parts of vinyl acetate resin, 30 parts of diphenylolpropane-formaldehyde resin and 30 parts of cellulose acetate in 300 parts of acetone.

Plauson<sup>86</sup> suggested the preparation of colloidal solutions of the suspensoid type from polymerized vinyl esters and an organic non-solvent, the mixture of resin and liquid being passed through a colloid mill. The resin may also be finely divided and dispersed in water.<sup>87</sup> The dispersion was applied by spraying and, after drying, the film was baked. Emulsions which could be used as coating compositions were formed when a solution of polyvinyl acetate in an organic solvent was added to water containing a protective colloid.<sup>88</sup>

An ink applicable to intaglio printing has been made by dissolving 50 parts of polyvinyl acetate in a mixture of 10 parts of cyclohexanone, 10 parts of ethyl acetate and 30 parts of alcohol, and incorporating a pigment consisting of 7.5 parts of lampblack and 2.5 parts of the calcium salt of the azo-dyestuff prepared from aniline and 2,6-naphtholsulphonic acid.<sup>89</sup> Before use the ink is diluted with alcohol. The composition is applied either by relief or lithographic printing. A viscous solution of vinyl compound has been employed as a binder for metal powders used in color printing.<sup>90</sup>

Solutions of vinyl resins may be used for coating wall paper, tapestries,<sup>91</sup> or fabrics,<sup>92</sup> for the impregnation of cloth to form shoe-stiffeners,<sup>93</sup> and for the sizing of yarns of viscose or other cellulose esters.<sup>94</sup> Scouring of the tightly twisted sized yarn with a solvent produces a crepe effect.<sup>95</sup> Vinyl esters have been employed for a combined impregnating and cementing of layers of fibrous material. In this manner sheets which are impervious to gases have been made and suggested

for use in gas masks.<sup>96</sup> Tissue paper coated with a vinyl acetate enamel has been advocated for cigarette tips.<sup>97</sup> A method of making articles impermeable to liquids is to condense on their cold surfaces the vapors of unpolymerized acetate, which is then polymerized by means of light, heat or catalysts (benzoyl peroxide).<sup>98</sup>

### ADHESIVES

An adhesive for joining various surfaces consists of a mixture of polymerized vinyl ester and isobutyl phthalate dissolved in methyl alcohol.<sup>99</sup> Polyvinyl acetate has been recommended for securing abrasive materials to steel discs.<sup>100</sup> It may be used also for making composite sheets from thin foils of cellulose derivatives.<sup>101</sup> Müller and Stelkens<sup>102</sup> prepared a powdered, dry glue containing polyvinyl acetate, ethylacetanilide and cellulose acetate or ethyl cellulose. A liquid adhesive is made up from 40 parts vinyl ester resin, 4-12 parts cellulose ester and 60 parts of a volatile solvent.<sup>103</sup>

Shatter-proof or safety glass consists of a sandwich layer of a tough plastic cemented between glass plates. Being colorless, transparent to both visible and ultraviolet light, non-yellowing, resistant to cold and possessing good adherence to glass, the vinyl resins show promise in this field. In most instances, however, their toughness is not sufficient to warrant using them without a layer of cellulose nitrate or acetate to impart the necessary strength.<sup>104</sup> Thus, a solution of polyvinyl acetate (in alcohol or ethyl acetate) may be employed for cementing glass sheets with films of cellulose derivatives.<sup>105</sup> Polyvinyl butyrate may be substituted for the acetate.<sup>106</sup> The layer of cellulose derivative may consist of cellulose acetate plasticized by a tartaric ester<sup>107</sup> or triacetin.<sup>108</sup> In this case adhesion is improved by mixing some of the plasticizer with the vinyl resin cement.<sup>109</sup>

When cellulose nitrate serves as the strengthening layer, there is a tendency to yellowing in sunlight. Bresser<sup>110</sup> observed that this defect may be diminished by using a mixture of cellulose nitrate and vinyl resin. Other cellulose derivatives which have been suggested for use in conjunction with polyvinyl esters in safety glass include the light-fast, fatty acid esters and mixed esters, e.g., the laurates, naphthenates and acetate-butyrate and butyrate-laurate mixtures.<sup>111</sup>

In another proposed form of safety glass, the layer of cellulose derivative is omitted and only a layer of vinyl resin placed between the sheets of glass. A

plasticizer<sup>118</sup> is mixed with the resin and the plastic applied either as a viscous solution or as a powder, followed by heating the composite under pressure.<sup>118</sup> The condensation product obtained by heating maleic anhydride with castor oil or 1,3-butylene glycol, when mixed with polyvinyl acetate, increases its adhesion to glass and renders it more resistant to cold.<sup>114</sup> The co-polymer of vinyl acetate and acrylate may be substituted for polyvinyl acetate.<sup>118</sup> These various types of plastics can be made to flow between heated sheets of glass by forcing them through fine copper tubes.<sup>116</sup> Walsh and Caprio<sup>117</sup> introduced vinyl acetate between glass plates and subjected the composite to pressure, thus forming the resin *in situ*. Wilson<sup>118</sup> suggested that a plasticizing agent, dibutyl phthalate, be employed as the strengthening layer.

In general, adhesives derived from vinyl acetate (also the methyl and ethyl esters of acrylic acid) may be utilized for gluing metal to metal, glass to glass, and textiles to leather. The bond is said to be flexible, durable, and resistant to water and to many organic solvents.<sup>119</sup>

### MOLDED PRODUCTS

When polyvinyl esters are heated to at least 100°C. in the presence of acid catalysts (lactic, hydrochloric or acetic acid or the chlorides of zinc or aluminum) the resulting products are elastic and more or less infusible and insoluble. If no catalysts are used the temperature must be raised to 200°C. Vinyl resins may therefore be employed to make buttons, umbrella handles, gears and other articles.<sup>120</sup> Objects are said to have been formed by spraying a concentrated solution of polyvinyl ester into a mold and allowing it to harden.<sup>121</sup> The method of injection molding has also been employed.<sup>122</sup>

Sheaths of polyvinyl acetate have been suggested as electrical insulators.<sup>123</sup> Rost<sup>124</sup> produced electrical cables by coating wires with layers of vinyl resins. Besides polyvinyl acetate, the substances resulting from the action of aldehydes on polyvinyl compounds<sup>125</sup> can be used. Dickie and Stafford<sup>126</sup> have described the preparation of films or sheets from the polyesters.

Medvedev<sup>127</sup> reported that the addition of polyvinyl acetate (up to 20 per cent) to cellulose nitrate films increased resistance to elongation. Rigidity, on the

<sup>118</sup> As a plasticizer 5-25 per cent of camphor may be used with dibutyl phthalate. A. Renfrew and J. S. B. Fleming, British P. 403,723, 1934, to Imperial Chem. Ind., Ltd.; *Chem. Abs.*, 1934, 28, 3549. French P. 788,994, 1934; *Chem. Abs.*, 1934, 28, 3204.

other hand, decreased. The presence of 10 per cent of this acetate improved the mechanical properties of denitrated cellulose nitrate.

Vinyl resins mixed with dispersions of rubber yield gutta-percha-like compositions<sup>120</sup> or with ground slate, cork and wood flour furnish linoleum substitutes or artificial leather.<sup>120</sup> About 10 per cent of vinyl acetate polymer in a rubber composition is asserted to give a vulcanized product that is resistant to gasoline.<sup>120</sup> Molding compositions have been made from vinyl resins and cellulose ethers<sup>121</sup> or esters.<sup>122</sup> Sound records are prepared from mixtures of polyvinyl acetate esters<sup>123</sup> and amorphous silica.<sup>124</sup> Products for this use are procured also by blending monomeric vinyl compounds and waxes and polymerizing the former *in situ*.<sup>125</sup>

Frank<sup>126</sup> suggested the formation of artificial silk threads by spinning solutions of cellulose esters or ethers and polyvinyl acetate. Rayon of improved softness, suppleness and increased resistance to water is obtained from cellulose xanthate and the xanthate of polyvinyl alcohol.<sup>127</sup> Dreyfus<sup>128</sup> employed mixtures of two vinyl acetate polymers having different viscosities. An artificial fabric is also made

shrinkage of these resins are wall panels and doors, both of which are molded around a fibrous core.

It is stated that the addition of polymerized fatty-acid vinyl esters, e.g., the acetate or stearate, to lubricating oils and greases improves their properties.<sup>141</sup> Alternatively, the monomer may be added to the hydrocarbon and polymerization effected *in situ* with boron fluoride. Oils thus treated have a lower cold test and a higher viscosity index.

#### MODIFIED ORGANIC-ESTER RESINS

The properties of vinyl resins may be modified either by treatment, for example with sulphur chloride to effect vulcanization,<sup>142</sup> or by incorporation of other materials during or after resinification. Thus, vinyl resins may be milled with rubber and the mixture vulcanized,<sup>143</sup> or lampblack incorporated with partially polymerized vinyl acetate before milling.<sup>144</sup> Rubber and vinyl compounds, heated under pressure, in the presence of a hydrocarbon solvent and sulphur and a heavy-metal chloride, yield a light-colored solution which may be employed as a lacquer.<sup>145</sup> Vinyl ester may be polymerized in a liquid medium (aliphatic hydrocarbon or alcohol) containing an emulsifying agent,<sup>146</sup> e.g., a cellulose derivative.

Plauson<sup>147</sup> made a complex resin (which was tougher than a straight phenol-formaldehyde resin) by heating 94 parts of phenol, 28-30 parts of paraformaldehyde and 86 parts of vinyl acetate in a closed vessel at 70-120°C. Unreacted ingredients were removed afterwards by heating at 100°C. under reduced pressure. Alternatively, phenol and formaldehyde may be combined first and the resulting resin heated with vinyl acetate under pressure. Reaction can be effected also in the presence of a solvent.

Vinyl esters condense with phenols when catalysts (hydrochloric or phosphoric acid, ferric, aluminum or zinc chloride) are employed.<sup>148</sup> Heating the condensate, with or without sulphur, causes it to harden. Fatty oils or long-chain fatty acids, factice or cellulose esters may be added prior to condensation. Vinyl esters can also be partially polymerized before condensation with phenols.<sup>149</sup> Niederl, Smith and McGreal<sup>150</sup> have studied the reaction between phenol and vinyl acetate in the presence of concentrated sulphuric acid. The product was an amorphous solid, a polymer of o-vinyl-phenol. It was assumed that phenoxyglycol acetate, first formed, is hydrolyzed and that the resulting glycol is dehydrated by the acid to phenyl vinyl ether which undergoes rearrangement to give o-vinyl-phenol. The latter compound is then polymerized by the acid. Phenyl acetate is also formed from phenol and vinyl acetate.<sup>151</sup>

<sup>150</sup> J. B. Niederl, R. A. Smith and M. E. McGreal, *J.A.C.S.*, 1931, 53, 3930.

<sup>151</sup> When phenols or alcohols are heated with vinyl esters in the presence of acid catalysts the vinyl group is replaced forming a new ester and acetaldehyde (H. Deutsch and W. O. Herrmann, British P. 314,646, 1928, to Consort. f. elektrochem. Ind. G.m.b.H.; *Brit. Chem. Abs. B*, 1929, 708. French P. 653,705, 1928; *Chem. Abs.*, 1929, 23, 3713. German P. 578,378, 1933; *Chem. If vinyl esters are passed at a high temperature through a reaction vessel packed with wood charcoal on which zinc oxide has been

Aldehyde<sup>188</sup> resins such as those obtained by treating acetaldehyde with sodium hydroxide may be combined with polymerized vinyl compounds by fusing the two together. These composite resins may be used for molding or as shellac substitutes.<sup>189</sup> It has also been proposed to mix urea-formaldehyde resins with vinyl resins to form a molding composition.<sup>184</sup>

Rosin and polyvinyl acetate, although not compatible, may be combined by heating to about 250°C.<sup>186</sup> The resin thus formed is soluble in benzene and linseed oil but insoluble in alcohol or alkalis. It probably consists, at least partially, of a polyvinyl ester of rosin as a result of the elimination of acetic acid. Linseed oil heated with a mixture of rosin and the polyacetate yields a varnish. Other acids (stearic, ricinoleic or naphthenic) and manila copal may be substituted for rosin. Replacement of the acetate group by other radicals (e.g., lactate, tartrate or citrate) may be effected by refluxing polyvinyl acetate with the appropriate acid.<sup>186</sup>

Polyvinyl compounds which are soluble or dispersible in water were prepared by Dreyfus<sup>187</sup> by the partial hydrolysis of the corresponding polyester. The partially hydrolyzed esters may be condensed with aldehydes to increase their resistance to wear and to weathering.<sup>188</sup> The water absorption of such resins is low and consequently resistance to humidity is improved. Lacquers prepared from them are somewhat similar to those from nitrocellulose in respect to toughness, are harder and more durable, and have an advantage over oil varnishes because of their greater speed of drying. The modified resins are soluble in a wide range of solvents including solvent naphtha mixed with alcohol, methyl and ethyl alcohol, acetone, dioxane, ethylene glycol monoethyl ether, ethyl acetate, chloroform and dichloroethylene.

Voss<sup>189</sup> made plastic substances, having a low solubility in water and organic solvents, by heating vinyl esters to about 150°C. in the presence of condensing agents, such as zinc chloride or hydrogen chloride. Robertson<sup>190</sup> reduced the fusi-

deposited, ketene, various ketones, acetaldehyde, acid anhydrides and vinyl ethers are produced. (H. Deutsch and W. O. Herrmann, German P. 515,807, 1927, to Consort. f. elektrochem. Ind. G.m.b.H.; *Chem. Abs.*, 1931, 25, 1537.) Acetic anhydride in a yield of about 77 per cent is obtained by boiling vinyl acetate under reflux with acetic acid and a little sulphuric acid (W. O. Herrmann and H. Deutsch, U. S. P. 1,856,251, May 3, 1932, to Consort. f. elektrochem. Ind. G.m.b.H.; *Chem. Abs.*, 1932, 26, 3820, British P. 288,549, 1928; *Brit. Chem. Abs. B*, 1929, 122.) If water is included in the mixture, the vinyl acetate decomposes to give acetic acid and acetaldehyde. (H. Deutsch and W. O. Herrmann, German P. 555,234, 1927, to Consort. f. elektrochem. Ind. G.m.b.H.; *Chem. Abs.*, 1932, 26, 5103.) By heating vinyl acetate with acetic acid in the presence of fuming sulphuric acid or a mercury compound, a yield of 85-90 per cent of the theoretical amount of ethylidene diacetate may be obtained. (F. W. Skirrow and J. Dick, U. S. P. 1,449,918, Mar. 27, 1923; *Chem. Abs.*, 1923, 17, 2290, Canadian P. 228,127, 1923; *Chem. Abs.*, 1923, 17, 1241.) Ethylidene diacetate yields decomposition products similar to those obtained from vinyl acetate. For example, ethylidene diacetate heated with monosodium phosphate or metaboric acid in an inert solvent, forms acetic anhydride and acetaldehyde (J. Koetschet and M. Beudet, U. S. P. 1,398,356, March 25, 1919; *Chem. Abs.*, 1919, 13, 1715) and heated with concentrated sulphuric acid it produces acetic anhydride and paraldehyde. (J. Koetschet and M. Beudet, U. S. P. 1,306,963, June 17, 1919; *Chem. Abs.*, 1919, 13, 2219.) If instead of adding the sulphuric acid directly, kieselguhr is saturated with it and then added, the side reactions are minimized and a high yield of pure acetaldehyde and acetic anhydride is obtained (H. Deutsch, German P. 391,874, 1921, addn. to 365,079, 1919, to Consort. f. elektrochem. Ind. G.m.b.H.; *J.S.C.I.*, 1924, 43, 811B).

<sup>190</sup> F. Robertson, U. S. P. 1,921,326, Aug. 8, 1932, to Carbide & Carbon Chemicals Corp.; *Chem. Abs.*, 1933, 27, 4263.

bility and solubility of polymerized vinyl esters by precipitating the resin in an alkaline solution. For example, 500 parts of an acetone solution containing 250 parts of vinyl resin were added slowly to 250 parts of a mixture of ethyl and isopropyl alcohols (equal parts by volume) containing 1 per cent of caustic soda. The mixture was stirred vigorously and 500 parts of water were added. The precipitated resin was filtered, washed with water and dried.

To remove air from compact masses of vinyl acetate resin, Renfrew<sup>161</sup> covered the block with a hydrocarbon oil and heated in an autoclave to 60°C. under a pressure of 400 lb. per square inch. The pressure was not released until the temperature had fallen to 20°C. (12 hours). Dreyfus<sup>162</sup> reported that incorporation of alkylolamines,  $\omega$ -aminoalkylamides of fatty acids or partially esterified polyhydric alcohols rendered the manufacture and manipulation of films of polyvinyl resins less difficult.

A mixed resin usable in lacquers is made by polymerizing a vinyl compound in the presence of an arylsulphonamide-aldehyde resin.<sup>163</sup> When polyvinyl esters are polymerized in liquids of the extracted stand-oil type, resins are obtained whose solutions serve as quick-drying lacquers. Oils employed in making such compositions are prepared by treating partially polymerized drying oils with solvents, for example, the higher alcohols or esters such as ethyl malonate,<sup>164</sup> which remove the nonpolymerized portion leaving the highly polymerized residue.<sup>165</sup> Further addition of oil or cellulose derivatives to the vinyl-oil condensate can be made.<sup>166</sup>

The product from polyvinyl esters and stand-oil extract is known as Olovine.<sup>167</sup> This forms hard, colorless, water-resistant films of high gloss, which are difficult to saponify and which do not turn yellow on aging. Cobalt salts accelerate their drying. Olovine in butyl acetate can be used with nitrocellulose as a lacquer.<sup>168</sup> Mixed with fibrous fillers it can be employed for phonograph records.<sup>169</sup>

Lawson and Sandborn<sup>170</sup> mixed vinyl compounds with nonpolymerized drying oils and then polymerized the composition in the absence of water. Heuck,<sup>171</sup> on the other hand, recommended using emulsions of unsaturated oils in water. Rosin and rosin esters can be added to the vinyl esters prior to polymerizing.<sup>172</sup> Plauson<sup>173</sup> made rubber-containing lacquers by heating rubber, vinyl acetate, acetic acid and trinitrophenol with a volatile hydrocarbon solvent. The addition of 5 per cent of a polyvinyl ester to chlorinated rubber is said to give a varnish base.<sup>174</sup>

light from a mercury arc, yields a vulcanizable product approaching rubber in elasticity.<sup>176</sup> A similar result is obtained if the protein be suspended in vinyl acetate with the addition of benzoyl peroxide and heated. Emulsions of mixtures of butadiene and vinyl compounds<sup>176</sup> may also be polymerized to rubber-like substances.<sup>177</sup>

Resins from vinyl chloroacetate are susceptible to modification by replacement of the chlorine. For example, treated with pyridine, polyvinyl chloroacetate yields a polyvinylammonium base which is soluble in water and useful in dyeing.<sup>178</sup> Polyvinyl chloroacetate also reacts with the alkali compounds of organic acids, phenols or alcohols, in a liquid which is a solvent for the polymer, to give pale-colored, chlorine-free resins. Sodium salts of drying oil acids, potassium phenolate, sodium glyceroxide or sodium butyl phthalate, used in this way, furnish a variety of resin types.<sup>179</sup>

Vinyl esters are capable of undergoing heteropolymerization by reaction with maleic anhydride and other  $\alpha,\beta$ -unsaturated acids. Voss and Dickhäuser<sup>180</sup> slowly heated a mixture of 86 parts of vinyl acetate, 50 parts of maleic anhydride and 0.6 parts of benzoyl peroxide under reflux. They obtained a light-colored, transparent resin in the form of a hard block which could be pulverized. The resin is soluble in acetone and in aqueous alkali solutions but is insoluble in alcohol and in benzene and thus differs from unmodified vinyl resin. A mixture of equal parts of styrene, vinyl acetate and maleic anhydride in acetone, heated in the same way, gives (after distilling off the solvent) a colorless, homogeneous, tough block which can be turned or planed. These heteropolymers may be hydrolyzed to water-soluble products. Morrell and Samuel<sup>181</sup> report that maleic anhydride and vinyl acetate do not react in the absence of a catalyst. Aqueous solutions of polyvinyl acetate-maleic acid polymers are recommended for the sizing and dressing of textiles<sup>182</sup> and they may be used in the preparation of color lakes<sup>183</sup> and of aqueous dispersions of dyestuffs and sulphur.<sup>184</sup> The polymers may be further treated with compounds such as glycerol capable of reacting with the anhydride groups.<sup>185</sup> Thus treated, the resins are insoluble in alkalies. Another heteropolymer is formed by heating vinyl acetate and trichloroethylene with a small quantity of benzoyl peroxide. This chlorine-containing polymer is a viscous liquid which hardens at ordinary temperatures.<sup>186</sup> Some of the trichloroethylene enters the reaction; the remainder acts as a solvent for the polymerized ester.

## POLYVINYL INORGANIC ESTERS

In comparison with the organic polyvinyl esters, the polymers of the inorganic esters have a lower degree of solubility and are much less stable when heated. Acetylene is the basic material from which the monomers are prepared, although ethylene addition products, for example, ethylene dichloride, may also be used.

## PREPARATION OF VINYL HALIDES

Vinyl halides are most conveniently prepared from the dihalogen-substituted ethanes. Vinyl chloride is obtained by treating ethylene dichloride with alcoholic potash<sup>187</sup> or with potassium hydroxide dissolved in methanol.<sup>188</sup> Ethylidene dichloride and sodium ethylate may also be used.<sup>189</sup> Dropped slowly into a saturated alcoholic solution of potassium hydroxide heated under reflux on a water bath, ethylidene dichloride begins reacting at about 35°C. (ethylene dichloride needs a slightly higher temperature). The reaction goes on slowly without further heating, producing a continuous evolution of vinyl chloride.<sup>190</sup> Vinyl chloride may be obtained by passing ethylene dichloride or ethylidene dichloride over hot contact masses such as pumice,<sup>191</sup> alumina<sup>192</sup> or active charcoal.<sup>193</sup> Using the last catalyst and ethylene dichloride a temperature of 230-350°C. was satisfactory. Both acetylene and vinyl chloride are formed by heating ethylene dichloride to 800°C., or a lower temperature in the presence of steam.<sup>194</sup> The production of acetylene, rather than of vinyl chloride, is favored by the presence of diluents, reduced pressure or increase in time of heating. Trichloroethane when treated with zinc, aluminum or iron at 50-120°C. in the presence of water or steam<sup>195</sup> produces vinyl chloride.

Acetylene and gaseous hydrogen chloride react at 180°C. in the presence of metallic chlorides to yield vinyl chloride.<sup>196</sup> Mercuric chloride on silica gel is an especially active catalyst, forming vinyl chloride even at 25°C.<sup>197</sup> Herrmann and Baum<sup>198</sup> used metal halides of the second and fifth groups (barium and bismuth chlorides) supported on activated silica gel. At 160-200°C., activated carbon itself is a catalyst.<sup>199</sup>

Vinyl chloride is also formed by the reaction of hydrogen chloride on nascent acetylene. Plauson<sup>200</sup> treated calcium carbide with concentrated hydrochloric acid at 60-95°C. in the presence of a catalyst (a mixture of a mercury and a copper salt). Reaction occurs without a catalyst if the pressure is increased above atmospheric, although some of the vinyl halide is polymerized under these conditions. Vinyl chloride distills off as it is formed; and, if a stream of hydrogen chloride

*Courtesy Plastics Division, Carbide and Carbon Chemicals Corp.*

FIG. 134.—Extrusion of Vinylite Plastic.

is passed through the reaction mixture during the operation, the yield is almost quantitative. Small quantities of zinc, aluminum or tin chlorides accelerate the addition of hydrogen chloride to give vinyl chloride, but ferric chloride accelerates formation of dichloroacetaldehyde, which is normally present in small amounts as a by-product.

Ostromislensky<sup>201</sup> passed purified acetylene through a 10 per cent solution of hydrochloric acid containing mercuric chloride and obtained vinyl chloride. Ac-

<sup>200</sup> H. Plauson, U. S. P. 1,445,168, Feb. 12, 1923; *Chem. Abs.*, 1923, 17, 1481. Canadian P. 227,823, 1923; *Chem. Abs.*, 1923, 17, 1241. British P. 154,120, 1920, to H. O. Traun's Forschungslaboratorium G.m.b.H.; *J.S.C.I.*, 1923, 41, 437A.

cording to Nieuwland and Foohey,<sup>202</sup> vinyl chloride is formed when acetylene is conducted into a solution containing cuprous chloride and ammonium chloride and saturated with hydrogen chloride. If both cuprous and cupric chlorides are present, an equilibrium mixture of cis- and trans-dichloroethylene is formed. Cupric chloride solutions do not absorb acetylene in the absence of cuprous chloride. Perkins<sup>203</sup> prepared vinyl chloride by passing acetylene at 65°C. through an aqueous solution containing about 12 per cent of hydrogen chloride and about 40 per cent of catalyst. The latter consisted of equal amounts of cuprous chloride and calcium chloride. Additional hydrogen chloride was supplied to maintain the concentration, and vinyl chloride was isolated from the issuing gaseous mixture. Toussaint<sup>204</sup> made vinyl chloride from acetylene and hydrogen chloride using mercuric chloride dissolved in anhydrous stannic chloride as a catalyst.

Acetylene reacts with hydrogen bromide to form vinyl bromide.<sup>205</sup> An 80 per cent yield can be obtained by treating a mixture containing 1.5 parts of acetylene and 1 part of hydrogen bromide by volume with actinic rays at 0°C.<sup>206</sup>

According to Plauson,<sup>207</sup> the addition of hydrogen halides to acetylene hydrocarbons takes place smoothly and rapidly at 100-120°C. under a pressure of 1-2 atmospheres. By increasing the pressure and raising the temperature when all the acetylene has reacted, polymerized products may be obtained without the necessity of isolating the intermediate halides.

#### POLYMERIZATION OF VINYL CHLORIDE

Vinyl chloride<sup>208</sup> and bromide<sup>209</sup> polymerize readily on standing and rapidly under the influence of light. The chloride, exposed to sunlight, forms under the conditions of treatment an amorphous, insoluble body having a specific gravity of 1.406, and melting with decomposition above 130°C.<sup>210</sup> If exposure to light is not too long, the polymer is soluble in chlorobenzene and the solution can be used as a lacquer. Films of the material are transparent, tough and noninflammable. Softened by mastication with chlorobenzene, it can be pressed and used as a celluloid substitute.<sup>211</sup>

According to Guyer and Schütze,<sup>212</sup> vinyl bromide is not polymerized by nitric acid or by some metals such as copper or zinc. Some polymerization was effected by lead dioxide, nickelic oxide on diatomaceous earth, and aluminum or iron and zinc foil. Hydrogen peroxide was apparently the most effective agent. Iron and bronze surfaces inhibited polymerization.

Plotnikow<sup>213</sup> observed that solutions of vinyl chloride in ethyl alcohol, acetone, carbon tetrachloride, methyl alcohol, ether, and toluene, when exposed to the action of ultraviolet light at temperatures of 15-25°C., deposited a white powder. In the

presence of salts of manganese, cobalt, nickel, copper, vanadium and uranium, reaction was catalyzed and took place in visible light.<sup>224</sup> Uranyl salts in sunlight were quite effective. The product resembled rice powder and was slightly soluble in acetone, methyl and ethyl alcohol, more soluble in benzene, carbon tetrachloride and carbon bisulphide, and very soluble in phenyl acetate. From those solvents in which it was fairly soluble, the polymer was recovered as an elastic film which lost its elasticity on keeping. When mixed with 40 per cent of French turpentine, 40 per cent of cedar oil, 65 per cent of pine oil or 60 per cent of camphor, yellow masses were obtained. Thirty per cent of castor oil converted it into a somewhat sticky, light gray mass, and with 60 per cent of copaiba balsam it yielded a dark wax-like mixture. With 70-75 per cent of castor oil or 75 per cent of pine oil, a vaseline-like mass was obtained. Jellies were produced on mixing with 50-70 per cent of aniline or 65-70 per cent of tetralin (tetrahydronaphthalene); while with 40 per cent of tetralin, 50 per cent of Peru balsam or 23 per cent of rosemary oil, it gave a solid, elastic mass. Flumiani<sup>225</sup> regarded the gels formed by polyvinyl chloride as relatively simple in comparison with such substances as gelatin and agar. He also found that the product from photopolymerization in the presence of uranyl nitrate was miscible with nitrobenzene, acetophenone, phenanthrene and naphthalene, giving solutions of varying degrees of dispersion.<sup>226</sup>

Ostromislensky<sup>227</sup> isolated what he considered to be several different types of polyvinyl chloride based on their solubility. The first of these ( $\alpha$ -polymer) is soluble in acetone and in chlorobenzene and is formed by the action of ultraviolet light in the presence of a catalyst (such as a soluble lead salt). If polymerization is continued, the product ( $\beta$ -polymer) is insoluble in acetone although still soluble in chlorobenzene. Further polymerization results in an insoluble body ( $\gamma$ -polymer), but if the reaction is interrupted just before the stage of complete insolubility is reached, the material will swell when treated with strong solvents ( $\delta$ -polymer). The  $\beta$ -polymer yields transparent films which remain flexible much longer than films of the  $\alpha$ -polymer. They may be plasticized by dichlorobenzene, chloronaphthalene, naphthalene, diphenylmethane, acetophenone, o-chlorophenol, benzyl chloride, ethyl benzoate, glycol diacetate or anisole. In the polymerization<sup>228</sup> of vinyl chloride by ultraviolet light, any  $\alpha$ -modification which has not been entirely converted into the  $\beta$ -form may be removed by extracting it with acetone. The  $\beta$ -polymer can also be obtained from the  $\gamma$ - or  $\delta$ -forms by heating them with aniline, quinoline, nitrobenzene or benzophenone. When polymerization is carried out in solution, the formation of insoluble material is retarded and is prevented almost entirely if chlorobenzene, ether, alcohol or tetrachloroethane are used as solvents.

Lawson and Werntz<sup>229</sup> produced the  $\alpha$ -polymer of vinyl chloride by heating the unpolymerized chloride at 90-120°C. in a solvent and in the presence of a catalyst such as benzoyl peroxide, ozone or barium peroxide. The solvents proposed were ethylene dichloride, methyl alcohol, chlorobenzene and ethyl acetate. It was suggested that this polymer be used for molding and as a coating. If, in addition to benzoyl peroxide, trioxymethylene is employed to catalyze the reaction, the  $\gamma$ -form is obtained.<sup>230</sup> Tetrahydrofurfuryl alcohol was recommended by Law-

son<sup>221</sup> as a high-boiling solvent for brushing-lacquers containing polyvinyl chloride. The  $\beta$ -polymer is partially soluble in this liquid. Dibenzylin (dibenzyl ether of glycerol) can be used as a plasticizer, the addition of 1 part of this ether to 3 parts of the  $\alpha$ -polymer yielding soft and flexible films.<sup>222</sup> The  $\alpha$ -polymer is also compatible with drying oils and may be blended with them to form a varnish.<sup>223</sup> Dykstra<sup>224</sup> recommended  $\alpha$ -polyvinyl chloride, polyvinyl chloroacetate and other resins containing chlorine as fluxes for soft soldering.

Courtesy Plastics Division, Carbide and Carbon Chemicals Corp.

FIG. 135.—Rubberless Army Raincoats Made by U. S. Rubber Company.

As mentioned above, ozone is a catalyst for the polymerization of vinyl chloride. In using ozone, air containing it is passed through a solvent for 2 hours, after which the vinyl compound is added. For example, Lawson<sup>225</sup> dissolved 17 g. of vinyl chloride in 69 g. of ozonized methanol and heated the solution for 5 hours in a sealed tube at 120°C. He obtained 7 g. of resin, composed entirely of the  $\alpha$ -polymer. In place of heating, the solution can be exposed to sunlight. A small proportion of water in the solvent has no adverse influence on the reaction. Hydro-

chloric acid (about 0.5 per cent) also has a catalytic effect. Using such a small amount of acid, the color of the polymer is not darkened appreciably.<sup>280</sup> Larger proportions of acids may be employed provided ethylene oxide is the solvent.<sup>287</sup> Young and Douglas<sup>288</sup> employed lead tetraethyl as a catalyst. A mixture of 70 parts of vinyl chloride, 30 parts of acetone and 1.4 parts of lead tetraethyl was heated in an autoclave for 20 hours at 80°C. A white, viscous resin solution was obtained.

The four forms of polyvinyl chloride described by Ostromislensky are insoluble in aromatic hydrocarbons. Lawson and Wernitz<sup>289</sup> have obtained a new form, lower in the polymeric series than the  $\alpha$ -form, by dissolving vinyl chloride in a benzenoid hydrocarbon, adding a catalyst and heating the solution. A mixture of 1500 parts by weight of vinyl chloride, 1000 parts of toluene and 45 parts of benzoyl peroxide was passed through a long lead-lined tube at 115-120°C. under a pressure of 500 pounds per square inch furnished by nitrogen gas. Seventeen hundred and seventy parts by weight of a light brown solution were obtained, having an acid number of 6, a viscosity of about 0.5 poise at 20°C. and containing 42.6 per cent solids. This was equivalent to a yield of 50.3 per cent of toluene-soluble polyvinyl chloride. The new polymer gave solutions of much lower viscosity than the other forms. While a 30 per cent solution of the  $\alpha$ -polymer is a gel at room temperature, the hydrocarbon-soluble polymer in ethyl acetate showed a low viscosity. It also differed from the  $\alpha$ -polymer in being incompatible with drying oils. A formula for an enamel containing this polymer consists of 16 parts of resin, 2 parts of dibutyl phthalate, 36 parts of solvent naphtha, 27 parts of toluene and 19 parts of titanium dioxide.<sup>290</sup>

A method for obtaining more uniform products of a high degree of polymerization has been suggested by Klatte and Müller.<sup>281</sup> They stopped the reaction and distilled off the monomeric form when there was yet about 50 per cent of it present. This procedure was found to permit a more uniform distribution of the catalyst and more exact separation of the remaining monomeric vinyl halide. For example, 1000 parts of vinyl chloride were passed in the gaseous state through a quartz tube illuminated by a mercury-vapor lamp. After recondensation of gas to the liquid state, 10 parts of barium peroxide and 10 parts of acetic anhydride were added. The mixture was heated in an autoclave for 10 hrs. at 35-45°C. The monomeric form was distilled off leaving about 350 parts of pulverulent, white polymer. Under the same conditions without the irradiation only about 250 parts of polyvinyl chloride were produced.

Vinyl halides, either alone or mixed with other polymerizable substances, may be polymerized while emulsified in water.<sup>282</sup> By coagulating the dispersion of rubber and polyvinyl halide formed by mixing a vinyl halide with latex and then polymerizing, plastic masses have been formed.<sup>283</sup> By heating vinyl halides under pressure, Voss and Dickhäuser prepared substances resembling celluloid.<sup>284</sup>

Prolonged heating of vinyl chloride in a closed vessel with a catalyst results in a polymer of the insoluble type. The reaction is more rapid if the vinyl chloride

is first exposed to the rays from a mercury arc.<sup>285</sup> Resins of which more than 75 per cent are insoluble in toluene have been prepared by heating vinyl chloride in a liquid the solvent power of which toward the resinous product is not appreciably more than that of toluene, e.g., an aliphatic hydrocarbon or alcohol. The temperature is kept below 60°C.<sup>286</sup>

Staudinger, Brunner and Feisst<sup>287</sup> investigated the polymerization of vinyl bromide and chloride exposed to ultraviolet light. The latter compound, for example, yielded polymers which were not soluble in the monomer, therefore no viscous solution or syrupy liquid was formed as the first step. Instead, there was separation of a solid phase, a mixture of low and high polymeric halides. Usually the average degree of polymerization was about 50, i.e., the union of about 50 molecules of vinyl chloride. The structure of polyvinyl chloride is represented as a long chlorinated hydrocarbon chain

in which the end groups are combined with solvent molecules, catalyst groups, or possibly are saturated by formation of rings.<sup>288</sup> The lower members of the polymer series are the more soluble and can be partially separated by fractional solubility in benzene or carbon disulphide. Molecular-weight determination is difficult on account of the low solubility in the cold, and, if the solution is heated to aid solubility, the polymer breaks down easily. These polymers are also sensitive to light and become discolored after a time. Soluble polyvinyl halides are of the hemi-colloid type and the highest polymer that could be obtained had a degree of polymerization of 100. Above this value the polymers are insoluble and correspond to the  $\gamma$ -polymer of Ostromislensky. The polymers produced by irradiating solutions of vinyl halides are more soluble than those prepared from the pure halides. It seems to be a general rule that dilution lowers the degree of polymerization of the product.

#### POLYMERIZATION OF OTHER HALOGEN-SUBSTITUTED ETHYLENES

Vinyl bromide is similar to vinyl chloride in the readiness with which it polymerizes, the change occurring when the liquid is exposed to sunlight.<sup>289</sup> The polymer is a solid, amorphous body, insoluble in water, alcohol and ether. The specific gravity of the material is 2.075. Boiling alcoholic potash extracts no bromine unless the treatment is continued for a very long time. The presence of light volatile hydrocarbons greatly retards the polymerization,<sup>290</sup> and, according to Kutscherow,<sup>291</sup> a trace of iodine hinders the reaction in diffused light.

Besides vinyl chloride and vinyl bromide, certain of the other halogenated ethylenes show a tendency towards polymerization. This applies, however, only to the dihalogen compounds of unsymmetrical structure,<sup>292</sup> such as  $\text{CH}_2=\text{CCl}_2$ ,  $\text{CH}_2=\text{CBr}$ , and  $\text{CH}_2=\text{CClBr}$ . Symmetrically substituted compounds like  $\text{CHCl}=\text{CHCl}$  and  $\text{CHBr}=\text{CHBr}$  are relatively stable, as is also trichloroethylene,  $\text{CHCl}=\text{CHCl}=\text{CHCl}$ .

$\text{CCl}_2$ , which is not spontaneously polymerized or oxidized when kept in contact with oxygen. The group,  $\text{CH}_2=\text{C}=\text{}$ , is apparently necessary for this type of polymerization. Compounds of fluorine and iodine are more stable than those of the other halogens. For example, vinyl iodide<sup>344</sup> oxidizes easily but does not readily polymerize, whereas difluoroethylene,  $\text{CH}_2=\text{CF}_2$ , undergoes neither of these reactions. When one of the fluorine atoms is replaced by bromine to form fluorobromoethylene,  $\text{CH}_2=\text{CFBr}$ , the resulting product is easily oxidized and polymerizes to a solid body.<sup>345</sup> Chlorobromoethylene,  $\text{CH}_2=\text{CClBr}$ , quickly changes to a solid, amorphous polymer. Biltz<sup>346</sup> allowed its polymerization to progress for 8 days, obtaining a polymer,  $(\text{CH}_2=\text{CClBr})_x$ , insoluble in most of the common solvents. It is slightly soluble in hot nitrobenzene and in molten naphthalene. Dibromoethylene,  $\text{CH}_2=\text{CBr}_2$ , is a liquid which easily changes to a polymeric solid of density 3.053, insoluble in water, alcohol and ether.<sup>347</sup> Chloronitroethylene,  $\text{CH}_2=\text{CClNO}_2$ , in the presence of sodium bicarbonate, is also transformed into a solid.<sup>347</sup>

Staudinger and Feisst<sup>348</sup> studied the polymerization of asym-dichloroethylene.<sup>349</sup> This liquid polymerizes very quickly in the light but also to the extent of 90 per cent when kept for 6 days in the dark. The polymer is very similar to polyvinyl chloride in appearance and in solubility, and its structure is represented as a long chain:

The number of groups of the monomer,  $-\text{CH}_2-\text{CCl}_2-$ , in the chain is between 50 and 100. The polymeric material is completely saturated. When heated above  $120^\circ\text{C}$ . it chars and some hydrogen chloride is eliminated. When reduced with red phosphorus and 70 per cent hydriodic acid at  $170^\circ\text{C}$ ., it formed a mixture of hydrocarbons which could be separated into two fractions, one having a molecular weight of 1400-1500 and the other having one of about 2400. This is considered significant evidence that the polymer consists of a long chain-structure. When the polymer is heated with aniline for 14 days, almost complete elimination

of halogen is accomplished and a benzene-soluble product,  $(-\text{CH}_2-\overset{\textstyle |}{\text{C}}=\text{NC}_6\text{H}_5)_x$ , results.

#### USE OF VINYL HALIDE RESINS

Vinyl halide resins, plasticized with various agents, such as tung or other natural drying oils<sup>350</sup> (particularly when blown), waxes and dialkyl phthalates,<sup>351</sup> or condensation products of polybasic acids, polyhydric alcohols and monobasic acids<sup>352</sup> (containing more than 6 carbon atoms), have been employed as coating agents. One coating composition, for example consisted of 16 parts of polyvinyl chloride (soluble in toluene), 19 parts of titanium oxide, 2 parts of dibutyl phthalate, 36 parts of solvent naphtha and 27 parts of toluene.<sup>353</sup> Another preparation con-

applications is the determination of the solubility in a 3 to 1 mixture of chlorobenzene and epichlorohydrin. It should take at least 15 cc. of the hot mixture to dissolve 1 g. and hold it in solution for 5 minutes after cooling to 20°C.<sup>598</sup>

Vinyl chloride polymers may be compounded with flexible alkyd resins<sup>599</sup> and fillers by heating at approximately 95°C. for ½ hour. After shaping, the product is cured for about 22 hours at 80-100°C.<sup>600</sup> Semon<sup>601</sup> prepared a resilient, rubber-like composition by dissolving 1 part of highly polymerized vinyl chloride at an elevated temperature in 0.5-4.0 parts of solvent which consisted of 2 parts of o-nitrodiphenyl ether and 1 part each of dinitrobenzene and dinitrotoluene. On cooling, the solution gelled and then was a corrosion-resistant electrical insulator. Thompson<sup>602</sup> has suggested a method of attaching such rubber-like materials to metals. He made a glue by mixing some of the polyvinyl halide with a fusible resin and then dissolving the mixture in a solvent. This glue was applied to the metal and the solvent allowed to evaporate. Then the rubber-like material was pressed on and the joint heated. One class of insoluble polyvinyl halide plastics (Koroseal) includes compositions of translucent appearance possessing colors ranging from pale amber to dark brown. The properties vary from those of hard rubber to those of gelled rubber cement. These plastics have exhibited good resistance to aging and light-cracking.<sup>603</sup>

Melamid<sup>604</sup> obtained a substitute for linseed oil by the reaction at 100°C. of allyl or vinyl bromide and solutions of hydroxybenzyl alcohols (from m- and p-cresols and formaldehyde) in 20 per cent aqueous caustic soda. The product was diluted with water and the solution extracted with ether or acetone. After distilling off the solvent, a viscous light brown liquid was obtained which solidified in the air. Any initial condensation product of a phenol with formaldehyde may be further treated in alkaline solution in this manner, and the allyl or vinyl ethers of dihydroxydiarylmethane thus formed are clear viscous transparent liquids, solidifying on exposure to the air.<sup>605</sup> Plauson<sup>606</sup> also made a composite vinyl chloride-phenol-formaldehyde resin by incorporating the chloride with the phenol resin at the time of its formation. A mixture of 94 parts of phenol, 65 parts of hexamethylenetetramine and 65 parts of polymerized vinyl chloride was stirred and heated to about 80°C. An exothermic reaction occurred and finally a clear, homogeneous liquid was obtained which gradually changed into a solid, tough mass.<sup>607</sup> Vinyl chloride has been condensed with phenols in the presence of aluminum or ferric chloride and the products polymerized by ultraviolet light.<sup>608</sup>

Voss and Dickhäuser<sup>609</sup> made a heteropolymer by heating a mixture of 80 parts of vinyl chloride, 100 parts of maleic anhydride, 0.5 part of barium peroxide

and 1.2 parts of acetic anhydride in an autoclave for 16 hours at 80°C. The product was a white powder, soluble in water and containing 14 per cent chlorine. Jordan, Hopff and Kühn have prepared heteropolymers of vinyl halides, or vinyl cyanide and stand oils.<sup>300</sup>

When benzene is treated with vinyl chloride in the presence of aluminum chloride at a low temperature, the main products are asym-diphenylethane and an anthracene-type resin. A trace of iodine causes a decrease in the amount of resin.<sup>301</sup> According to Dreyfus,<sup>301</sup> polymerized 2-chloropropene heated with a solution of disodium tartrate furnishes an impregnating and sizing agent. In this instance the chlorine is replaced by a tartrate radical.

Adhesives may be obtained by subjecting polyvinyl chloride to a complementary chlorination,<sup>302</sup> or by depolymerization of the chlorinated material (effected by heating) and incorporating wetting agents.<sup>303</sup>

### CO-POLYMERIZATION OF VINYL ESTERS

The most important vinyl ester co-polymer is that obtained by polymerization of a mixture of vinyl chloride and vinyl acetate.<sup>304</sup> The resulting resin differs from the polymer of either co-reactant and in many respects is superior to either. It also differs from a mixture of the polymers prepared separately and blended. When equivalent amounts of each component are mixed and polymerized, the structure of the co-polymer may be pictured as a long chain, the alternate links of which are vinyl chloride and vinyl acetate units:

In general, the actual distribution of the components in the chain is dependent entirely on chance collisions and on the relative proportions of the reactants.

### POLYMERIZATION

A mixture of vinyl chloride and acetate can be polymerized in any way applicable to the two reactants alone, that is, by the action of heat or light in the presence of a catalyst. Lawson<sup>305</sup> has described a continuous process for producing the co-polymers dissolved in a liquid by passing a heated solution of the two vinyl compounds through a long tube under pressure.

A mixture of 60 parts by weight of ethyl acetate, 30 parts of vinyl chloride, 10 parts of vinyl acetate and 2.7 parts of benzoyl peroxide was forced through a lead-lined, steel reaction-tube having a volume of 800 cc. at a pressure of 200 pounds per square inch. The rate of flow was 800 cc. per hour and the temperature 120°C. The interpolymerized product obtained in this manner gave a slightly yellow solution which yielded a white polymer when precipitated with alcohol. The yield of polymer

<sup>305</sup> One form of the resin known as Vinylite, made by Carbide & Carbon Chemicals Corp., is said to be a co-polymer of vinyl chloride and vinyl acetate. The various grades differ in the proportions of the two vinyl compounds used. For the use of Vinylite in the preparation of artificial eyes, see J. L. Travers, U. S. P. 1,993,121, Mar. 5, 1935, to M. H. Russell; and in the manufacture of laminated products, J. D. Cochran, Jr., U. S. P. 1,997,359, Apr. 9, 1935, to the Formica Insulation Co.

<sup>306</sup> W. E. Lawson, U. S. P. 1,867,014, July 12, 1932, to E. I. du Pont de Nemours & Co.; *Chem. Abs.*, 1933, 26, 4611. British P. 319,588, 1929; *Brit. Chem. Abs. B*, 1931, 666. French P. 682,123, 1929; *Chem. Abs.*, 1930, 24, 4806.

was 66 per cent, the concentration of vinyl chloride in the material being 72 per cent. In another case a solution of 1000 g. of vinyl chloride, 250 g. of vinyl acetate and 57 g. of benzoyl peroxide in 650 g. of ethyl acetate was forced through the tube. The product was very viscous. The yield of polymer was about 70 per cent and the concentration of vinyl chloride in the resin was 80 per cent.

The polymers from vinyl acetate adhere well to various surfaces, but coatings made from them are too soft and too soluble in common solvents. They are easily scratched and also are damaged by contact with preparations containing alcohols. Polyvinyl halides, on the other hand, give more resistant films, but

gested is as follows: 25 grams of dry resin are dissolved in 1 liter of acetone, and 140 cc. of this is run into an agitated mixture of 1280 cc. of water and 320 cc. of ammonium hydroxide, the solution being maintained at 30-35°C. The addition of 5 cc. of concentrated hydrochloric acid flocculates the suspension. The small aggregates obtained after washing and drying are easily broken up.

A low-viscosity vinyl polymer has been prepared by adding rosin to the mixture of vinyl acetate and vinyl chloride before polymerizing.<sup>300</sup> Young and Douglas<sup>301</sup> increased the melting point of the resin resulting from the polymerization of a mixture containing about 80 per cent of vinyl chloride and 20 per cent of vinyl acetate by heating the resin in a liquid medium in the presence of benzoyl peroxide at 65-75°C. They also obtained a substantially uniform vinyl resin of relatively low fusion point by extracting the polymerized mass with toluene in which the desired fraction dissolved.<sup>302</sup>

#### USES OF THE VINYL ACETATE-CHLORIDE CO-POLYMERS

The co-polymers of vinyl chloride and vinyl acetate may be roughly divided into two groups: one containing a major proportion of vinyl acetate, making them applicable for coatings where adequate solubility is required, and the other containing a major proportion of vinyl chloride, more suitable for molding purposes.<sup>303</sup>

Co-polymers may be fractionated by extraction with solvents.<sup>304</sup> Thus an insoluble gel precipitates from a mixture of toluene (90 parts) and resin (10 parts). The soluble fraction has an average molecular weight of 1500 and melts at 60-80°C. The insoluble portion has an average molecular weight of 2500 and does not melt below 125°C. The latter fraction gives films which have greater strength and are tougher and more resistant to heat than the original polymer. The soluble portion may be used for coatings and the insoluble fraction for moldings such as dentures.<sup>305</sup>

#### COATINGS

If 30 parts of vinyl chloride and 70 parts of vinyl acetate are polymerized together, a resin is formed which is soluble in such solvents as toluene, benzene and butyl acetate, and which is less inflammable than polyvinyl acetate alone. The resin is compatible with nitrocellulose and can be used in lacquers.<sup>306</sup> A wax added to such a lacquer increases its water-resistance.<sup>307</sup> The paper liners for closures to food containers have been coated with a plasticized vinyl acetate-chloride resin.<sup>308</sup>

Lacquers having a vinyl chloride-vinyl acetate-resin base show promise in several directions. They are stable to light and resistant to ordinary salt and alkaline

solutions and to acid solutions of concentration up to about 20 per cent.<sup>299</sup> As a paint for plastered walls, a vinyl-resin lacquer has been found to give good coverage per gallon. No "sealer" is necessary. An increased coverage which is sometimes found may be due to the fact that the lacquer does not penetrate but tends to stay at the surface. The dense film thus formed is reported to be easier to keep clean than the more porous film of ordinary paint.

### MOLDINGS

One disadvantage of polyvinyl chloride as a molding resin is its tendency to decompose at the temperature required in the molding operation. This decomposition is especially troublesome in the presence of iron and iron compounds, and it is necessary to avoid fillers containing iron, such as the usual calcined filler containing hematite. The iron compound is attacked, forming ferric chloride which causes the mass to become porous and brittle during the mixing process. The addition of 10 per cent of vinyl acetate to the chloride before polymerization produces a resin which is much more stable than polyvinyl chloride alone. Although polyvinyl acetate is not as resistant to moisture as might be desired, the small amount required in conjunction with polyvinyl chloride does not seriously affect the co-polymer in this respect. Co-polymers containing a high proportion of the chloride find application in such fields as dentures,<sup>300</sup> and sound records.<sup>301</sup>

As a material for sound records vinyl resin has partially replaced two plastics: (1) shellac formerly used in making standard records, vinyl resin showing a better quality of tone, and (2) celluloid as used for home recording, where the advantage of vinyl resin from the standpoint of fire hazard is obvious. The vinyl compound gives a quieter record and one which is much lighter. The old 16-inch record weighed 20 ounces, while the 12-inch vinyl record having the same playing time weighs only 4 ounces. Shellac records require very careful packing in wooden boxes but the vinyl records, owing to their flexibility, can be packed in paper boxes. The addition of a filler to the vinyl resin is desirable, as it gives a cheaper composition with improved resistance to wear by the needle. In order to make a satisfactory filled compound it is necessary to add plasticizers. Solid Aroclors and Halowaxes are commonly used but others, such as dibutyl phthalate and triphenyl phosphate, produce similar results although they are more expensive.

A variety of articles have been fabricated from these resins. For example, Groff has prepared sound records, linoleum and a transparent, flexible wrapping material. He used 80 parts of vinyl chloride and 20 parts of vinyl acetate and graded the product by the solubility in toluene.<sup>302</sup> The resin may be mixed with a filler, e.g., silica or mica, or a plasticizer, e.g., dibutyl phthalate.<sup>303</sup> Stabilizers, which may be incorporated also, include alkaline earth metal soaps, resinates, oxides or carbonates, aromatic amines which are insoluble in water<sup>304</sup> and olefin oxides such

<sup>299</sup> G. F. Steigerwalt (*Agr. Eng.*, 1933, 14, 154; *Chem. Abs.*, 1934, 28, 873) has reported that Stonite (a Vinylite coating material) is a satisfactory coating for silo walls.

<sup>300</sup> Two dentures on the market having a basis of Vinylite are known as Vidon and Resovin. See also N. B. Nabbett, *Dental Cosmos*, 1933, 75, 1035; *Chem. Abs.*, 1934, 28, 1536. For the preparation of dentures, see F. Groff, U. S. P. 1,990,903, Feb. 12, 1935, to Carbide & Carbon Chemicals Corp.; *Chem. Abs.*, 1935, 29, 2361. French P. 745,661, 1934; *Chem. Abs.*, 1934, 28, 6593. F. Schmidt (British P. 412,442, 1934; *Chem. Abs.*, 1934, 28, 7443) reported that co-polymers, which have subsequently been halogenated, may be used also for dentures.

as epichlorohydrin or phenoxypropene oxide.<sup>305</sup> Davidson and McClure<sup>306</sup> report that one advantage Vinylite resins have as dentures is the fact that they are not thermosetting and so may be repaired and remolded repeatedly. Davidson and McClure also describe the construction of a model three-room apartment using Vinylite for windows, doors, flooring, walls and furnishings.

### COMMON USES OF VINYL RESINS

In the preceding sections, mention has been made of certain uses to which the various vinyl resins have been applied. A few investigators have suggested uses to which several or all types of vinyl resins are adapted. These applications may be classified as coating agents,<sup>307</sup> impregnating agents, adhesives and moldings.<sup>308</sup>

### COATING AND IMPREGNATING AGENTS

Solvents in which the various resins will dissolve have been mentioned previously. It has also been noted that plasticizers may, or may not, be used with vinyl resins, depending upon the requirements of the coating. Among the plasticizers which may be employed are the phthalic esters such as dibutyl, dicyclohexyl, diethyl, cyclohexyl butyl or cyclohexyl amyl phthalates<sup>309</sup> and the benzyl ethers of glycerol such as dibenzylin.<sup>300</sup> Derivatives of aromatic sulphonamides (Abracols),<sup>301</sup> tributyl phosphate (Plastoflex), tricresyl phosphate (Lindol),<sup>302</sup> butyl stearate, camphor, triacetin and ethylacetanilide are also compatible with these resins. Moss<sup>303</sup> suggests phenolic derivatives such as diphenylolpropane, diphenylolcyclohexane and triphenyl phosphate.

Another group of substances which can be mixed with vinyl resins include soluble phenol-formaldehyde resins.<sup>304</sup> Among these should be mentioned the condensation products of aldehydes and such phenol derivatives as salicylic acid and phenol ethers.<sup>305</sup> Coating compositions containing vinyl resins, oil-modified alkyl resins and plasticizers have been proposed.<sup>306</sup>

The use of fatty oils as plasticizers without a blending agent should be avoided. However, Carr has made a stencil-sheet composition using dibutyl phthalate and peanut oil.<sup>307</sup> Ten parts of a 30 per cent solution of polyvinyl acetate in toluene were mixed with 3.5 parts of peanut oil, 1 part of dibutyl phthalate and 2 parts of aluminum stearate. The stencil-sheet was then made by applying this mixture to Yoshino paper.

Polyvinyl resins have been suggested by Seel to coat the sides of photographic

<sup>312</sup> K. W. Carr, U. S. P. 1,530,960, Nov. 10, 1931, to Ditto, Inc.; *Chem. Abs.*, 1932, 26, 816.

paper. The emulsion was applied over the vinyl resin. This coating of vinyl compound made the paper waterproof, and therefore the finished print dried faster.<sup>300</sup> Gutta-percha has been mixed with vinyl resins and polymerized oils to form waterproof coatings for use in making sandpaper.<sup>301</sup>

It has been suggested that vinyl halide resins be employed for the impregnation of fabrics, thus rendering them oil-resistant and applicable for covering the vulcanized rubber on insulated wires.<sup>310</sup> Moss used such fabrics also in electrical insulation.<sup>311</sup> He reports that the products are water-resistant. When applied to fabrics made of cellulose acetate the wear-resistance is increased. Also the products have less tendency to slip or ladder. Fabrics thus treated may be used in making the tops for fancy shoes.<sup>312</sup> A composition made from a vinyl resin, a wax, a gum and a plasticizing agent has been suggested for waterproofing cellulose-acetate sheets.<sup>313</sup>

Not only cloth, but also paper has been impregnated with vinyl resins. Lawson reports that paper which has been dipped into solutions of plasticized vinyl resins is stronger than ordinary paper. It is tough and pliable.<sup>314</sup> Groff<sup>315</sup> has added the impregnating agent to the pulp while it was being processed instead of after the paper was finished. Porous paper strengthened with vinyl resins has been used in the manufacture of vacuum-cleaner bags.<sup>316</sup>

Walsh and Caprio<sup>317</sup> introduced an unpolymerized vinyl compound between the layers of materials which they wished to stick together and then polymerized the compound through the action of heat and catalysts. In this manner, they were able to unite wood, metal, rubber, celluloid and ceramic materials. Fife<sup>318</sup> employed polymerized vinyl resins which will flow under heat and pressure to unite the layers of composite sheet materials. Substances like the polyvinyl resins have been used to fasten photographic films to supports so that they can be handled during development.<sup>319</sup> Sound-record disks have been made by attaching the layer on which the sound track is cut with a metal plate using vinyl resins as the adhesive.<sup>320</sup> Vinyl resins have been suggested as binders for the molded calcium-carbide cakes which are used in the generation of acetylene.<sup>321</sup>

As was mentioned under the uses of polyvinyl acetate, considerable work has been done in the attempt to prepare safety glass from vinyl resins. One of the compounds which has been suggested for this purpose is that resulting from the heteropolymerization of methyl acrylate and vinyl cyanide.<sup>322</sup> Similarly, Shep-

pard<sup>322</sup> has used a solution of polyvinyl acetate or the heteropolymer of vinyl acetate and chloride as an optical cement.

Related to the formation of safety glass is the manufacture of glass substitutes. For example, Greider<sup>323</sup> utilized the ultraviolet-transmitting characteristics of polyvinyl esters in the production of a transparent film to be used as a window glass or for light filters. The film was reinforced by supporting it on wire mesh or woven fabric. Plasticizers were mixed with the vinyl resin when it was to be used in this way.<sup>322</sup> Another glass substitute of the same type consisted of wire netting which was coated with a polymerized vinyl compound and then dipped into a cellulose acetate solution to fill in the holes. The vinyl derivative served to protect the wire from the weather.<sup>322</sup>

It has already been mentioned that cellulose esters and ethers can be incorporated into molding compositions made from polyvinyl acetate. One method of mixing any of the vinyl resins with these materials is to polymerize the vinyl ester while in solution with the cellulose compound.<sup>327</sup> Rubber-polyvinyl acetate lacquers have also been mentioned previously. One use to which a mixture of 1 per cent of polymerized vinyl compound with rubber has been applied is as a binder for molding sand. The mixture was dissolved in a volatile solvent along with a sulphur compound to produce vulcanization.<sup>328</sup> Another process in which such mixtures can be used is the manufacture of electrical insulation.<sup>329</sup> A leather substitute comprises rubber together with a resin resulting from the co-polymerization of vinyl chloride and acetate.<sup>330</sup>

The polyvinyl esters have relatively good adhesion to metals. This has been utilized in the preparation of molds for thermoplastic materials. The mold of vinyl resin was coated by spraying the metal on it. If the final coat consisted of a high-melting substance, a low-melting one (zinc or tin) was applied first.<sup>321</sup> A similar use is to interpose a layer of polyvinyl compound between a metal coating and another synthetic resin.<sup>323</sup> However, Groff states that in producing composite molded articles having both metallic and resinous portions the metallic portions should be sized with a cumarone or an alkyd resin in order to cause the polyvinyl compound to adhere.<sup>323</sup>

Not only the acetate, but any of the polyvinyl esters may be spun into artificial silk. The thread after it is formed is stretched in several stages.<sup>324</sup> For example, mixtures of polymerized vinyl esters, benzene, and plasticizers are extruded as threads, which are stretched while hot and cooled under tension.<sup>325</sup> Interpolymers of vinyl chloride (70-93 per cent) and vinyl acetate have been proposed

for filaments and films.<sup>336</sup> The resin in acetone is extruded into a precipitating medium, removed under tension at such a rate that only a superficial film is formed, and dried. Sheets or threads made in this manner can be stabilized to a desired form or dimension by subjecting them to the action of heat or swelling agents and then cooling or drying.<sup>337</sup>

There are a number of applications of vinyl resins which do not fall into the categories of lacquers, adhesives and molding materials. For example, by dusting fusible polyvinyl resins over a printed page while the ink was yet damp and then heating, relief print has been produced.<sup>338</sup> Vinyl resins have also been used as plasticizing agents for alkyd resins<sup>339</sup> and as stabilizing agents in suspensions of synthetic resins in organic liquids.<sup>340</sup> Branchen<sup>341</sup> has described a method for recovering both the cellulose ester and vinyl resin from scrap sheeting material, the vinyl resin being extracted with 1,2-dichloropropane. An oil-soluble dyestuff has been prepared by coupling diazotized p-nitroaniline with vinyl resins.<sup>342</sup> Dispersions of vinyl resins have been used to deluster rayon.<sup>343</sup> The chewing gum named "Chex" contains a vinyl resin and sulphur as two of the ingredients.<sup>344</sup> Another chewing gum base has been made by adding an equal weight of masticated crepe rubber to polyvinyl chloride while the latter was being treated in a roll mill.<sup>345</sup>

## Chapter 52

### Polyvinyl Alcohol. Polyvinyl Acetals

Vinyl alcohol has not been isolated; polyvinyl alcohol is the only form in which it is known. The simple alcohol should be formed by the hydrolysis of monochloroethylene but this reaction yields the isomeric acetaldehyde.

These two substances represent the keto and enol forms, of which the keto form (acetaldehyde) is the stable one. Although the enolic form (vinyl alcohol) is unknown, the acetylated compound is capable of existence as vinyl acetate:

Polyvinyl alcohol has to be prepared indirectly and this is accomplished through polyvinyl acetate. Under the influence of catalysts and light, vinyl acetate yields polyvinyl acetate:

where  $n$  may vary between 20 and 900.<sup>1</sup> Hydrolysis of polyvinyl acetate with either alkali or acid yields a mixture of polyvinyl alcohols which are insoluble in benzene and chloroform. The simpler alcohols form colloidal solutions in cold water, formamide, ethylene glycol and glycerol. The more complex derivatives can be dispersed in these solvents by heat. The solubility of the polyvinyl alcohols suggests the behavior of starch. The essential difference between the two types of compounds is that the polyvinyl alcohols are much more stable<sup>2</sup> and do not yield monomeric units by hydrolytic cleavage.

On the basis of evidence from other linear polymers<sup>3</sup> the structure of polyvinyl alcohol can be considered to be

Another structural formula suggested<sup>4</sup> is of the cyclic type:

<sup>1</sup> H. Staudinger and A. Schwalbach, *Ann.*, 1931, 488, 8; *Brit. Chem. Abs. A*, 1931, 1032.

<sup>2</sup> H. Staudinger, K. Frey and W. Starck, *Ber.*, 1927, 60, 1782; *Brit. Chem. Abs. A*, 1927, 1051.

<sup>3</sup> H. Staudinger, "Hochmolekularen organischen Verbindungen," J. Springer, Berlin, 1932, 40. See Chapter 4.

<sup>4</sup> H. Staudinger, K. Frey and W. Starck, *loc. cit.*

There is also the possibility of the formation of smaller rings by etherification:

or by dehydration followed by cyclization:

The alcohol groups retain their reactivity in the macromolecule and may be acetylated or benzoyleated. Neither procedure, however, can be carried to completion; in other words, the acetylation of polyvinyl alcohol will not yield as completely an acetylated compound as is the polyvinyl acetate obtained by polymerizing vinyl acetate. The methyl ether prepared from polyvinyl alcohol resembles methylated starch. Attention has already been called to the marked similarity of solubility behavior of starch and polyvinyl alcohol. The parallelism may be carried further by comparing the 6-membered ring structures of polyvinyl alcohol shown above with the conventional formula for starch:

#### PREPARATION OF POLYVINYL ALCOHOL

As mentioned previously, polyvinyl alcohol is prepared from its polymeric esters by hydrolysis with acid or alkali.<sup>5</sup> A uniformly light yellow or brown product results with caustic saponification. When acid is used, the nature of the original substance determines the color and density of the final product, which may vary widely. Acid hydrolysis is carried out by passing hydrogen chloride into a boiling alcoholic solution of the ester or by boiling the alcoholic solution for several hours with a little sulphuric acid.<sup>6</sup> Langenbeck and Baltes<sup>7</sup> have investigated the effect of catalysts upon the hydrolysis of polyvinyl acetate. For their work 1.7 g. (0.002 mol) of a 10 per cent solution of polyvinyl acetate was dissolved in quinoline along with 3 cc. of a 1 per cent solution of potassium acetate dissolved in isopropyl alcohol. The quantity of catalyst varied from 0.002 to 0.01 mol. The solutions were sealed in glass tubes and heated in the vapor from boiling cyclohexanol (approximately 160°C.). The extent of hydrolysis was determined by saponifying the resulting distillate of isopropyl acetate with 0.1 *N* barium hydroxide solution. The results obtained are given in Table 55 (on page 1056). Polyvinyl alcohol can be separated from its compounds by extraction with anhydrous mono- or polyhydric alcohols, using an acid or basic saponification catalyst.<sup>8</sup>

<sup>5</sup> W. O. Herrmann and W. Haehnel, *Ber.*, 1927, 60, 1658; *Chem. Abs.*, 1928, 22, 214.

<sup>6</sup> A. Skrabal and A. Lahorka (*Monatsh.*, 1927, 48, 459; *Brit. Chem. Abs. A*, 1927, 1148) have studied the kinetics of the hydrolysis of freshly prepared unimolecular vinyl acetate and find that the velocity of hydrolysis is much more rapid than in the case of ethyl acetate.

<sup>7</sup> W. Langenbeck and J. Baltes, *Ber.*, 1934, 67, 387; *Chem. Abs.*, 1934, 28, 3379.

TABLE 55.—Catalytic Hydrolysis of Polyvinyl Acetate.

Catalysts	Quantity of Catalyst in Mols	Reaction Time in Hours	Volume of 0.1N Ba(OH) <sub>2</sub> in cc.	
			With Catalyst	Without Catalyst
Benzyl alcohol . . . . .	0.01	10	4.55	2.21
Naphthylcarbinol . . . .	0.005	15	4.92	3.00
Glycolanilide . . . . .	0.002	15	7.40	3.00
Benzoylcarbinol . . . .	0.002	15	5.02	2.26

Herrmann and Haehnel<sup>9</sup> stated that polyvinyl alcohol behaves like a typical reversible colloid. The fact that it can be purified by dialysis helps to confirm the colloidal explanation. This alcohol would have to function chiefly as a hydrosol since it is insoluble in almost all other substances. In contradistinction to gelatin it swells only slightly in water and dissolves readily at ordinary temperatures. With hot glycerol or glycol, polyvinyl alcohol gives a clear solution that gelatinizes on cooling. The alcohol in phenol, however, remains liquid on cooling if there is a trace of water present. With dispersoids, e.g., metals, oxides, hydroxides and sulphides, polyvinyl alcohol acts as a protective colloid. Its molecular weight was estimated to be 868 by the osmotic method. The acetylation reaction: polyvinyl alcohol → polyvinyl acetate, is accomplished by pressure and heat. On heating polyvinyl alcohol to 200–220°C. under 30 atmospheres pressure, it forms a hard, horny mass which is less soluble in glycerol, glycol and water than the original polymer, and more soluble in hot linseed and castor oils. Acetylation of this solid product results in the formation of typical polymeric vinyl acetate.

Polyvinyl alcohol will, according to Herrmann and Haehnel,<sup>10</sup> react with bromine to form addition compounds, which are converted by boiling water into a black insoluble form of the alcohol. A similar addition reaction occurs with chlorine. It is stated that the alcohol cannot be oxidized by potassium permanganate or by chromium trioxide, though oxidation with nitric acid gives oxalic acid. With benzaldehyde, polyvinyl alcohol reacts to form an acetal, and with formaldehyde, compounds allied to amyloform of starch (amyloextrin treated with formaldehyde) are obtained. The latter substances are somewhat more elastic than amyloform, are insoluble and do not swell in water, are fusible, and are more stable towards heat. When treated with dilute acids and alkalis they slowly lose formaldehyde. The aldehyde derivatives have attained some industrial significance, and will be discussed later. The polyvinyl alcohols resemble crude rubber in that they can be vulcanized with sulphur, the addition of accelerators being optional. Cold vulcanization gives soft gum-like substances which are elastic, and hot vulcanization yields a hard black mass which can be readily worked.

The method of Herrmann and Haehnel for converting polyvinyl acetate into polyvinyl alcohol, as already described, may be applied to production on a large scale.<sup>11</sup> The polymer of vinyl alcohol is obtained as an odorless, white, water-soluble powder. By evaporating a water solution of the polymer, films or thin sheets of high elasticity and strength may be obtained. Polyvinyl alcohol is also formed in the saponification of polyvinyl halides. Thus, from polyvinyl chloride with sodium hydroxide in the presence of light, and using uranyl nitrate as a catalyst, a 90 per cent yield of the alcohol is obtained.<sup>12</sup> According to Noller<sup>13</sup>

<sup>9</sup> W. O. Herrmann and W. Haehnel, *Ber.*, 1927, 60, 1658; *Chem. Abs.*, 1928, 22, 214.

<sup>10</sup> W. O. Herrmann and W. Haehnel, *loc. cit.*

<sup>11</sup> W. O. Herrmann and W. Haehnel, U. S. P. 1,672,156, June 5, 1928, to Consortium für elektrochem. Ind. G.m.b.H.; *Brit. Chem. Abs.* B, 1928, 665. Canadian P. 265,173, 1926; *Chem. Abs.*, 1927, 21, 918.

<sup>12</sup> W. Haehnel and W. O. Herrmann, German P. 516,996, 1932, to Consortium für elektrochem. Ind. G.m.b.H.; *Chem. Abs.*, 1931, 25, 3018.

<sup>13</sup> C. R. Noller, U. S. P. 1,897,356, Feb. 14, 1932, to Eastman Kodak Co.; *Chem. Abs.*, 1932, 27, 2096.

polymerized vinyl acetate may be saponified with an alkali metal hydroxide in presence of an alcohol, such as ethyl alcohol, and sufficient water to prevent precipitation of the polymerized product. The latter is subsequently precipitated by adding alcohol. By treating polymerized vinyl alcohol with butyric acid anhydride a neutral butyrate results, which is a rubber-like, alcohol-soluble substance, from which elastic threads or membranes may be produced. When polymerized vinyl alcohol is melted with an equivalent quantity of aleuritic acid or trihydroxystearic acid, an aleuritinate or trihydroxystearate is obtained. Both of these substances are very hard, elastic and practically insoluble in most solvents. Herrmann and Haehnel<sup>14</sup> have also described vinyl glycolate, which is soluble in ammonia and in pyridine.

The polymerization of the vinyl esters,<sup>15</sup> which forms the first step in the production of the alcohols, can be carried out at 40-160°C. in the presence of a compound such as barium peroxide, benzoyl peroxide, percarbonates, persulphates, or perborates, together with organic acid anhydrides, but without solvents or diluents. Under such conditions the product is practically insoluble in ethyl acetate, alcohol or acetone. Saponification gives a water-soluble vinyl alcohol, the viscous water solutions of which are useful as dispersing media for dye pastes, sizing or dressing compositions.<sup>16</sup> The hydrolysis may be carried out with ethyl alcohol and sulphuric acid.

Klatte and Müller<sup>17</sup> employed ammonium hydroxide for the saponification of polyvinyl mixed esters. Polyvinyl acetate-chloroacetate, for example, with ammonium hydroxide gave a solid polyvinyl alcohol. Partial or complete saponification of the mixed polymerization products obtained by the co-polymerization of vinyl halides with styrene, butadiene or acrylic ester, or of acrylic ester with vinyl acetate<sup>18</sup> also yields substances having some of the properties of polyvinyl alcohols.<sup>19</sup> Products of high viscosity are formed by the addition of a boron compound, e.g., an ester of boric acid, fluoboric acid, or acetofluoboric acid, to polymerized vinyl alcohol, the mixture being maintained in a neutral or slightly alkaline condition. In place of polyvinyl alcohol itself, vinyl alcohol which has been partly etherified or esterified may be used.<sup>20</sup>

#### USES OF POLYVINYL ALCOHOL

Polyvinyl alcohol may be employed for the production of resists (preparations which prevent dyes from adhering to fabrics) under vat colors. The fabric is printed with an oxidant, such as sodium m-nitrobenzenesulphonate or sodium dichromate, and an aqueous solution of a polyvinyl alcohol. It is then dried and dyed with the vat dye. The polyvinyl alcohol is coagulated in the warm vat, and adheres to the printed portions of the fabric.<sup>21</sup> In printing with vat dyes (which need alkali for fixing them on the fiber), a paste free from alkali and containing polymerized vinyl alcohol as the thickening-agent may be used. The prints are subsequently treated in an alkaline bath.<sup>22</sup> The alcohols of very high viscosity

<sup>20</sup> French P. 745,942, 1933, to I. G. Farbenind. A.-G.; *Chem. Abs.*, 1933, 27, 4042.

<sup>21</sup> G. Torinus, U. S. P. 1,922,963, Aug. 15, 1933, to General Aniline Works; *Chem. Abs.*, 1933, 27, 5197. British P. 356,069, 1930, to I. G. Farbenind. A.-G.; *Brit. Chem. Abs. B*, 1932, 19. German P. 531,475, 1933; *Chem. Abs.*, 1931, 25, 5575.

<sup>22</sup> British P. 329,207, 1929, to I. G. Farbenind. A.-G.; *Chem. Abs.*, 1930, 24, 5510.

have found application in the sizing of fibers. Such polymers are obtained either by polymerizing the vinyl ester in the presence of a perborate and acetic anhydride and saponifying, or by the addition of a small quantity of borax to a polyvinyl alcohol of medium or low viscosity.<sup>22</sup>

Polyvinyl alcohols may be used in conjunction with other sizing agents and oils, fats, and waxes. Thus, an aqueous solution containing 0.2-0.33 per cent of sulphonated oil and 2-3.33 per cent of the alcohol is a representative sizing preparation. The size is equally suited for cotton, artificial silk or wool, and is readily removed by washing with warm water or 0.1-0.2 per cent soap solution.<sup>24</sup> Water-soluble derivatives of polyvinyl alcohol, including the products of the partial saponification of a polyvinyl ester, or those resulting from the condensation of an aldehyde and the alcohol, may be used instead of the polymerized alcohol itself.<sup>25</sup> For example, a fabric can be impregnated with a polyvinyl ester in an organic solvent. On drying, the fabric is treated with alkali or acid to produce complete or partial hydrolysis of the ester.<sup>26</sup>

Rayon or cotton may be sized with polyvinyl alcohol solutions having a viscosity 10 to 25 times that of an aqueous glycerol solution of equal concentration.<sup>27</sup> For sizing rayon, the incorporation of substances, e.g., fats, waxes or fatty acids, that reduce the adhesiveness of the aqueous alcohol solution, has been suggested.<sup>28</sup>

Jordan<sup>29</sup> prepared a composition for the coating of porous surfaces by emulsifying solutions of cellulose nitrate or acetate with an aqueous solution of polyvinyl alcohol.

A solution of polymerized vinyl alcohol in water serves as a stabilizer for hydrosols containing metals, metallic oxides or metallic sulphides.<sup>30</sup> The partially saponified polymerization products of vinyl acetate, dissolved in an anhydrous solvent, may be utilized as a binding medium in the production of plaster surgical bandages,<sup>31</sup> including those impregnated with plaster of Paris and other substances which set in water.

Relatively concentrated solutions of polyvinyl alcohols in water can be extruded through an orifice at raised temperatures and allowed to solidify to threads or ribbons. Fillers may be added, and the resistance of the product to water is believed to be improved by the incorporation of hydrophobic substances or by treatment with formaldehyde vapor at an elevated temperature.<sup>32</sup> The addition of a volatile organic liquid not itself a solvent for polyvinyl alcohol, such as ethyl alcohol, which promotes rapid evaporation of water, improves the uniformity of threads and tubes made in the above process.<sup>33</sup> Threads, so prepared, are said to be adaptable for medicinal and surgical use. The incorporation of 5-10 per cent of oxalic, malic or lactic acid in the polyvinyl alcohol surgical sutures is reported

to increase their capacity for being resorbed.<sup>44</sup> Polyvinyl alcohol has also been applied in the manufacture of photographic films. The rear side of a transparent cellulose film or glass plate emulsion support is coated with a layer of the alcohol containing an antihalation dye, which will act as a desensitizer in solution.<sup>45</sup>

A product stated to be useful for the manufacture of films and molded articles may be prepared by heating polyvinyl alcohol to 160°C. in order to render it water-insoluble. The heat treatment may be dispensed with in this conversion by using reagents capable of precipitating albumins, such as tannin or formaldehyde.<sup>46</sup>

### POLYVINYL ESTERS

Mixed esters of polyvinyl alcohol are formed by treating the polymerized alcohol with two or more acid halides, either together or in succession, and in the presence of an organic diluent and a tertiary base of the pyridine type. Compounds prepared in this manner may be used in the production of films, filaments, lacquers and coatings.<sup>47</sup> The mixed esters may be converted to an insoluble form by long heat treatment. As an example of this procedure, a mixture of polyvinyl alcohol, ethyl chloride, naphthenic acid chloride, chlorobenzene and pyridine bases may be heated to 35-40°C. for 24 hours. The ester is separated by treating the crude solution with methyl alcohol and filtering. It is used in acetone solution.

The partial hydrolysis of polyvinyl esters gives products which are employed as sizes or impregnating agents for textiles. Such a reaction occurs on heating polyvinyl acetate (with 90 per cent acetic acid containing sulphuric acid) at 40-60°C. until the polymer is soluble in 30-50 per cent aqueous ethyl alcohol. Another method for preparing compounds, which may be dissolved or dispersed in water, involves the esterification of polyvinyl alcohol with various acids such as lactic, tartaric, citric, malic, oxalic and maleic.<sup>48</sup> Voss and Starck<sup>49</sup> have reported that polymerized vinyl alcohol can be partially esterified to yield compounds soluble in organic solvents. The process, however, could not be utilized to produce water-insoluble esters. The extent of esterification is dependent upon the molecular weight of the acid radical, the maximum being obtained with acids of low molecular weight.

Polymerized vinyl acetate may be prepared directly from the polymerized alcohol by heating a solution of the latter in acetic anhydride with dry sodium acetate. An elastic mass of partially butylated polymerized vinyl alcohol is obtained on heating the alcohol with butyric acid.<sup>50</sup>

Combinations of polyvinyl esters and fatty oils are made by polymerizing vinyl esters in the presence of a polymerized fatty oil, usually in its "low-disperse phase." This phase is obtained by removing the non-polymerized portion with an aliphatic alcohol (propyl or higher) or an ester such as ethyl malonate. Oil varnishes, coating compositions, adhesives and plastics are made from these products.<sup>41</sup> A writ-

ing ink is prepared using a polyvinyl alcohol and a fatty oil to which pigments are added. White ink is made by incorporating zinc oxide.<sup>43</sup> Hydroxyalkyl and alkyl polyvinyl ethers are formed by the interaction of an alkylene oxide with a polyvinyl alcohol. The reaction is carried out under high pressure in the presence of inert gases, with the addition of such basic accelerators as dimethylaniline, trimethylamine, pyridine or alkalis. Thus, a polyvinyl alcohol prepared by the saponification of a polymerized vinyl acetate of high viscosity may be treated with ethylene oxide. Substituted polymers of this type may find application as thickening, dressing and sizing agents, and as plastics.<sup>44</sup>

#### VULCANIZED PRODUCTS FROM POLYVINYL COMPOUNDS

The treatment of polymerized vinyl alcohol or its derivatives with sulphur or sulphur compounds, as stated previously, leads to a reaction simulating the vulcanization of rubber. The properties of the product resemble the different qualities of soft and hard rubber according to the starting materials and the reaction conditions.<sup>45</sup> If polymeric vinyl alcohol is mixed with 1 per cent of sulphur and heated for 5 hours at 150°C. under a pressure of 10 atmospheres, there results a black, hard rubber-like material which can be worked by cutting, sawing or filing. A similar substance is formed by heating the alcohol with 2 per cent of sulphur and 2 per cent of piperidine as an accelerator for half an hour at 120°C. under 10 atmospheres pressure. Vulcanization can also be effected by covering polymerized vinyl alcohol at ordinary temperatures with a 10 per cent solution of sulphur monochloride in carbon disulphide. At the end of 24 hours, the crude resin is washed, giving a gray-colored plastic mass resembling vulcanized soft rubber. This process may also be carried out with the addition of fillers. For example, a mixture of polymeric vinyl alcohol, 25 per cent of ground slate and 1 per cent of sulphur was pressed for half an hour at 150°C. under a pressure of 100 atmospheres to yield a hard, slate-blue material.

#### CONDENSATION OF POLYVINYL ALCOHOLS WITH ALDEHYDES

The interaction of polymerized vinyl alcohol (derived from vinyl esters) with aldehydes furnishes a further group of substances which are of value as synthetic resins. Condensation products of rubber-like, plastic and elastic, or of hard and brittle character are obtained from alcohol and aliphatic aldehydes (e.g., formaldehyde, acetaldehyde).<sup>46</sup> (See Fig. 139.) An acid catalyst (e.g., zinc chloride, aluminum chloride, mineral acids) is used. It is also said that the use of a water-insoluble solvent (e.g., benzene) materially increases the yield.<sup>47</sup> Condensation probably occurs with elimination of water between the hydroxyl groups in the alcohol and oxygen in the aldehyde, giving an acetal grouping of the type shown below in the case where formaldehyde is employed.

The viscosity and solubility of the reaction product are dependent upon the quantity of acid employed.<sup>47</sup> The polymeric compounds may be vulcanized to hard substances resembling ebonite. This subsequent vulcanization is especially beneficial if unsaturated aldehydes such as acrolein have been used.<sup>48</sup>

The polyvinyl alcohol-aldehyde condensation may be carried out in such a way that the product is liquid and soluble in water. The essential conditions for water-solubility are the use of the minimum proportion of aldehyde and the avoidance of high temperatures.<sup>49</sup> Formalin used at its boiling temperature gives insoluble solid resins. With less reactive aldehydes such as benzaldehyde, aldol, butyraldehyde or glyoxal, larger proportions of the aldehyde and higher reaction temperatures may be utilized without forming solid products. The actual working conditions are indicated by the following examples:

Twenty parts of a polyvinyl alcohol of low viscosity are dissolved in 80 parts of water containing 2-3 per cent of sulphuric acid, and 25 parts of 30 per cent formaldehyde are added. The solution is kept at 60-65°C. until its viscosity has increased by at

FIG. 139.—Acetal of Vinyl Alcohol in Flaky Form.

least 100 per cent. The reaction solution may then be used directly for manufacturing emulsions of insoluble dyestuffs, for sizing, dressing or for printing. Alternatively, the reaction product may be isolated by precipitating it with alcohol, filtering by suction, washing and drying. In the case of benzaldehyde, 150 parts of 12 per cent aqueous polyvinyl alcohol are mixed with 20 parts of the aldehyde. The mixture is heated on a water bath until a test sample solidifies in the cold to a gelatinous mass. The polymeric derivative under these conditions is soluble in water, the solutions being, as before, considerably more viscous than those of the alcohol itself. Any excess of aldehyde in the above reactions may be removed by the addition of ammonium hydroxide. An acid catalyst may also be used. For example, 125 parts of a 25 per cent aqueous solution of polyvinyl alcohol are mixed with 15 parts of acetaldehyde and 1 part of concentrated hydrochloric acid. The resulting mixture is heated on a water bath until a test sample shows the desired viscosity, whereupon the heating is discontinued and the free acid neutralized.

In a similar procedure, Belloc<sup>50</sup> obtained a condensation product, without the isolation of polyvinyl alcohol, by combining polymerized vinyl esters with an aldehyde in hydrochloric acid. Condensation may, also, be carried out in an anhydrous medium to yield polymers recommended as substitutes for celluloid in the

<sup>47</sup> G. E. Zelger, French P. 769,010, 1934; *Chem. Abs.*, 1935, 29, 528.

manufacture of lacquers.<sup>51</sup> The general procedure may be illustrated by the reaction between polyvinyl alcohol and acetaldehyde, in which phosphoric acid is the condensing agent and methylene chloride is the solvent. The mixture is boiled and the water formed distills over with the methylene chloride. Hopff and Kuehn<sup>52</sup> have used aldehydes in other forms, including trioxymethylene, metaldehyde and methylal. Polyhydric alcohols, such as those made by reducing polymeric methyl vinyl ketone, polymeric acraldehyde, or by hydrolyzing polymeric methyl vinyl acetates may be condensed with aldehydes in the same way as vinyl alcohol itself.<sup>53</sup> The vinyl alcohol-aldehyde condensation products already described<sup>54</sup> may be dissolved in organic solvents, such as chlorinated hydrocarbons, glycol ethers, esters, alcohols, hydrocarbons, and used in the preparation of lacquers, coating compositions, adhesives, impregnating solutions and for making films. The solutions may contain dyes or pigments.<sup>55</sup>

In a method employed by Zelger,<sup>56</sup> powders, grains, filaments, films, plates, tubes and other diversified forms in which polyvinyl alcohol-aldehyde condensation products can be obtained, are shaped to their ultimate external state before undergoing aldehyde condensation.

A modified polyvinyl acetal has been recommended by Voss, Dickhäuser and Starck<sup>57</sup> for the manufacture of molded articles. The acetal is prepared by condensing a mixed polymerization product of vinyl acetate and vinyl oleate with butyraldehyde. Condensation products from polyvinyl alcohols and aldehydes may also be used as celluloid substitutes, and for the manufacture of sound records.<sup>58</sup> For example, Schmidt<sup>59</sup> has described such a record possessing the requisite qualities of strength, toughness and durability. For its preparation, 50 kg. of a polyvinyl alcohol-formaldehyde condensation product were kneaded with 50 kg. of a 2:1 mixture of alcohol and benzene, along with 2.5 kg. of the isobutyl ester of phthalic acid as a plasticizing agent. This mass may subsequently be molded with heat and pressure. Another molding composition, suggested for sound records, consists of one or more polyvinyl ester-aldehyde hydrolytic products combined with an ester wax or a metallic stearate as lubricant. Fillers, pigments, resins and plasticizers may be added.<sup>60</sup>

Furthermore, polyvinyl acetals, when used in conjunction with cellulose solutions of the viscose type, are stated to improve the mechanical properties and to impart enhanced gloss, durability and softness to artificial threads made there-

<sup>51</sup> British P. 403,750, 1934, to I. G. Farbenind. A.-G.; *Chem. Abs.*, 1934, 28, 3416.

from.<sup>61</sup> A representative procedure involves the addition of sodium hydroxide, carbon disulphide and a solution of polyvinylformal in an organic solvent to a solution of cellulose xanthate. Filaments are formed and spun into threads according to the methods used in the viscose process. Another spinning-solution contains cellulose acetate dissolved in a mixture of methylene chloride and alcohol together with a polyvinyl acetal.<sup>62</sup>

The polyvinyl alcohol condensation with aldehydes may be further modified if a substance capable of condensing with the aldehyde is introduced into the reaction mixture. Such compounds as phenol, aromatic amines, urea, gelatin, or casein may be used for this purpose. The products vary from horn-like or moldable masses and lacquer-base resins to water-soluble products which are applied as emulsifiers and tanning agents. Mild reaction conditions yield viscous water-soluble products and prolonged heating gives resins which are insoluble in water.<sup>63</sup>

#### CONDENSATION OF POLYVINYL ALCOHOLS WITH KETONES

The action of condensing-catalysts on mixtures of polyvinyl alcohols (or esters) and cyclic ketones yields condensation products. When, for example, polyvinyl alcohol, ethyl alcohol, benzene and methylcyclohexanone are heated to 80°C. with concentrated sulphuric acid, a resin is obtained in the form of a white powder.<sup>64</sup> These resins are soluble in water and also in organic solvents. Cyclohexanone, its 4-chloro derivative and 1-keto-tetrahydronaphthalene are other examples of ketones available for this purpose.

The constitutions of these condensation products have not yet been fully ascertained. However Kränzlein, Voss and Starck<sup>65</sup> assumed that the union takes place by the loss of water in which the hydrogen atoms are furnished by hydroxyl groups of the alcohol and the oxygen by the ketone group. For example, the condensation between polyvinyl alcohol and 2-methylcyclohexanone may proceed according to the following equation:

(The assumed result of the reaction between polyvinyl alcohol and the cyclic ketone, 2-methylcyclohexanone, is indicated on the following page.)

## POLYMERIZATION PRODUCTS OF VINYL ESTERS WITH ALDEHYDES

Ordinarily reaction between vinyl esters and aldehydes is slow, but at high temperatures and pressures condensation proceeds readily. For example, 0.1 part of acetaldehyde and 100 parts by volume of vinyl acetate heated in a bomb for 16 hours at 100°C. yield 66 parts of a product which is hard when cold but tough and rubbery when warm.<sup>66</sup> Resins prepared with a larger proportion of aldehyde are gummy, semi-liquid, or liquid substances. With 10-15 parts of aldehyde per 100 parts of vinyl acetate, the product has the consistency of chewing gum and can be used in the manufacture of the latter.

Esters such as vinyl butyrate or formate, or esters of higher molecular weight, give results similar to those obtained with vinyl acetate. Vinyl ethers, vinyl halides or other compounds containing ethylene linkages may be substituted for the esters. Similarly formaldehyde, paraldehyde, butyraldehyde or aldehydes of higher molecular weight may be used in place of acetaldehyde. Compounds of the acetal type may be employed under conditions such that they will liberate acetaldehyde. The reaction is inhibited by sulphur and certain sulphur compounds, and is retarded by iron and copper and some of their compounds. Vessels constructed of these materials must therefore be avoided, and glass, porcelain, enamel or aluminum used in their place. The presence of oxygen was found, in general, to accelerate the reaction and improve the yield, but it is doubtful if it is essential. A small amount of a catalyst such as hydrogen chloride may be added to the reaction system.<sup>67</sup> This reaction was found to be greatly facilitated by illumination. The effective part of the spectrum lies in the visible range, and the reaction mixture may accordingly be contained in a vessel of Pyrex and subjected to the light of a mercury arc. Good yields of resin are obtainable in the illuminated systems without the use of heat and pressure.<sup>68</sup> In this case oxygen was found to have very little effect either on the speed of reaction or on the product.

Matheson and Skirrow noted a connection between exposure of vinyl esters to oxygen and the ease of polymerization. In general, the esters treated with oxygen and exposed to light were active, whereas esters from which oxygen had been excluded during manufacture were inactive and would not polymerize. The conditions required in the case of polymerization were found to apply also to the reaction of vinyl esters with aldehydes and acetals.<sup>69</sup>

Aldehyde-polyvinyl ester condensations are usually carried out in the presence

<sup>66</sup> H. W. Matheson and F. W. Skirrow, U. S. P. 1,752,362, Aug. 20, 1929, to Canadian Electro Products Co., Ltd.; *Chem. Abs.*, 1929, 23, 5051.

<sup>69</sup> H. W. Matheson and F. W. Skirrow, U. S. P. 1,746,665, Feb. 11, 1930, to Canadian Electro Products Co., Ltd.; *Chem. Abs.*, 1930, 24, 1754.

of oxygen. It is also possible to use benzoyl peroxide in amounts varying between 0.01 and 1 per cent as a catalyst in the condensation reaction.<sup>76</sup> Leopold and Michael,<sup>77</sup> however, have obtained transparent to red resins by condensing a vinyl ester, such as the acetate, with aliphatic aldehydes or substances generating them, at temperatures of the order of 150°C. and pressures of 20 atmospheres. Para-formaldehyde and vinyl acetate under such conditions gave a yellow fusible resin. The absence of oxygen was emphasized as one of the conditions of this reaction. The products were said to be useful in the manufacture of spirit varnishes and polishes. The reaction of vinyl ester with acetaldehyde has also been carried out in the presence of toluene, the latter serving as a modifier for the reaction.<sup>78</sup>

Chewing gum can be manufactured from the condensation product of aliphatic vinyl esters and saturated aliphatic aldehydes by incorporating sugar and flavoring ingredients.<sup>79</sup> The condensation product used in the preparation of chewing gum is tasteless and insoluble in water or saliva, and is not as sticky as gum chicle. However, the synthetic resin possesses the desirable properties of gum chicle and does not harden on continued chewing. The derivative obtained from a polyvinyl ester and an aldehyde has been suggested for use in lacquers, varnishes, enamels and paints. The condensation product (presumably in the hard forms) is recommended as a substitute for shellac and other resinous binders.<sup>80</sup> Mixed with clay, rubber, sulphur, zinc oxide and coloring matter, it may also serve as a rubber substitute.<sup>81</sup> An emulsion, said to be adaptable for use in chewing gums, is prepared by heating a vinyl ester-aldehyde gum with a polyhydric alcohol such as ethylene glycol, cooling the mixture, and separating the resulting emulsion from the excess alcohol.<sup>82</sup>

The production of plastic materials by reaction between a polyvinyl ester in solution and an acetal has been reported.<sup>83</sup> The condensation is effected in absolute alcohol solution using hydrogen chloride as the condensing catalyst.

#### ALDEHYDE TREATMENT OF HYDROLYZED VINYL ESTER-ALDEHYDE PRODUCTS

Vinyl ester polymers and the vinyl ester-aldehyde products may be hydrolyzed by heating with dilute mineral acids and water to yield a gummy product.<sup>84</sup> Skirrow, Morrison and Blaikie<sup>85</sup> found that further condensations of these hydrolyzed or partially hydrolyzed materials with aldehydes yielded resinous substances which were, in general, harder and tougher than the gums from which they were formed. The exact nature of the product obtained in this manner depends on the amount and character of both the primary and the secondary aldehyde, the extent of

hydrolysis of the gum, and the nature and quantity of the acid catalyst used.<sup>80</sup> The following example illustrates the reaction conditions:

To 1000 parts by weight of the vinyl acetate-acetaldehyde gum (obtained by reacting vinyl acetate with 2.7 per cent of its weight of aldehyde) are added 2000 parts by weight of ethyl alcohol to form a solution. To this are added 450 parts of formalin solution and 25 parts of concentrated hydrochloric acid, and the whole allowed to react for 14 hours at approximately 100°C. in an autoclave. After recovery of the solvent and the ethyl acetate formed and removal of acid, the product is dried. The purified derivative is described as a molding resin which can be worked on hot rolls and mixed with the usual fillers.

The hydrolysis and secondary aldehyde reactions take place simultaneously. The hydrolysis proceeds to an extent of about 60 per cent as estimated by the total acid liberated, both free and as ethyl acetate. The use of less aldehyde in the primary condensation leads to a harder, tougher and stronger resin. Ethyl alcohol may be replaced by analogous solvents but its use has the advantage that the acetic acid is largely recovered as the ethyl ester.

The product of hydrolysis may be isolated if required, the whole operation being then conducted in two stages. Use of acetaldehyde in place of formaldehyde in the second stage of the condensation leads to substances which are less hard and tough. The primary gum-like product may be made with aliphatic vinyl esters other than vinyl acetate, and with various aldehydes. Thus, vinyl butyrate or propionate, butyraldehyde, propylaldehyde and other compounds of the same series all give similar results. The primary condensation products utilized in these reactions do not lend themselves to the manufacture of molding resins, since they lack physical strength and toughness, and have softening points which are generally too low.

Starting with a definite primary gum-like product the characteristics of the secondary aldehyde resins vary widely. Those resulting from limited hydrolysis are of low softening point which increases as the percentage hydrolysis is increased. The product of complete hydrolysis of the primary gum when condensed with an aldehyde gives a resin of very high softening point. The resins may be used either in the pure state or blended.

A polyvinyl resin (made by hydrolysis of the ester and reaction with an aldehyde) is employed in a composition for injection molding. Impact-strength promoters, lubricants, fillers and pigments are added.<sup>81</sup> This resin can be used for phonograph records<sup>82</sup> and for paints, varnishes and enamels<sup>83</sup> by the addition of necessary modifying constituents. Schmidt<sup>84</sup> prepared a celluloid substitute by kneading a polyvinyl alcohol-formaldehyde condensation product (100 kg.) with alcohol (60 l.) and benzene (30 l.) at 30°C. The major portion of the solvent was driven off on hot rolls, and the mass was compacted at 80°C. under a pressure of 20 kg. per sq.cm. The resulting block was cut into foils, dried and polished.

Saponification of the polymerization product of vinyl acetate and maleic anhydride, followed by heating of the product with formaldehyde, gives a material which is recommended for making resistant lacquers.<sup>85</sup>

Plastic materials are obtained by reacting a polyvinyl ester with ethylidene diacetate, in the presence of anhydrous alcohol and an acid catalyst. They may be

employed in the preparation of lacquers, varnishes, enamels, shellac substitutes (in record manufacture) and molded articles.<sup>60</sup>

### MISCELLANEOUS PRODUCTS

The polymerization of a mixture of a vinyl halide with less than 43 per cent by weight of a vinyl compound containing oxygen, e.g., the acetate, in presence of benzoyl peroxide and a stabilizer (calcium stearate or titanium oxide) yields a uniform moldable resin.<sup>61</sup> It is advocated for the manufacture of sound records, and floor or wall surfaces. After the incorporation of large amounts of plasticizers, the mixed polymers may be utilized as a lacquer resin, or insulating material. Saponification of the polyvinyl ester can be followed without cessation of operation by condensation of the resulting polyvinyl alcohol with aldehyde, using hydrochloric acid as medium and ethyl alcohol as accelerator. The condensation products are employed for varnishes, motion picture films, records and artificial fibers.<sup>62</sup> Hard thermoplastic products are obtained from a mixture of vinyl and acrylic esters by saponification with aqueous sodium hydroxide and treatment with sulphuric acid. The resultant product may be used for making films, filaments and coating compositions.<sup>63</sup>

Yacca gum with vinyl ester polymers and vinyl ester-aldehyde products yields a material possessing lower water-absorbing and higher warp-resisting qualities.<sup>64</sup>

Vinyl resins are used in making composite articles with metals. The metal is corroded before applying the resin and the coated object is heated and cooled under pressure.<sup>65</sup>

Polyvinyl alcohol, as previously noted, may be treated with an alkylene oxide at ordinary or raised temperature and pressure, to yield water-soluble products used as thickeners, sizes or plastic masses.<sup>66</sup> An accelerator such as a tertiary organic base may be employed. Vinyl acetate forms one constituent of an adhesive for uniting celluloid to glass (either vinyl acetate, glyceryl phthalate and a plasticizer or vinyl acetate, formaldehyde-toluene sulphonamide and dibutyl phthalate).<sup>67</sup> A splinterless glass<sup>68</sup> can be made by interposing between sheets of glass a highly viscous and elastic layer of polyvinyl alcohol. The polymerized ester, either alone or condensed with aldehydes, is also used in manufacturing laminated glass.<sup>69</sup> When vinyl ester resins undergo partial acetal transformation, they become more soluble in the usual solvents and can be utilized for making films, adhesives and molding compositions. The flexibility and water-resistance of the films are increased when a non-drying oil is added.<sup>70</sup>

Polyvinyl alcohols react with  $\alpha$ -haloalkyl ethers in the presence of a hydrogen halide and a catalyst (zinc, iron or aluminum chloride) to form compositions for molding, insulating materials, adhesives and manufacture of films and threads.<sup>71</sup>

On adding monochlorodimethyl ether drop by drop to a boiling chloroform suspension of polyvinyl alcohol, a white solid is precipitated.<sup>99</sup>

Another process for the manufacture of artificial threads has been advanced,<sup>99</sup> in which a polymerized vinyl compound dissolved in cyclohexanone is utilized together with a softening agent. This is spun into a precipitating-bath containing acetic acid, sodium perchlorate or sodium thiocyanate, and the swollen threads are stretched in several increasing steps and then shrunk, before collecting on the receiving device.

Among other applications, polyvinyl alcohol has found use in food preparations. Haehnel and Herrmann<sup>100</sup> have proposed the utilization of polyvinyl alcohol and its derivatives as gelatinizing agents in the manufacture of fruit jellies. The addition of about 1 per cent of polymerized vinyl alcohol to ice cream preparations before freezing is said to improve the texture of the product by eliminating the formation of ice crystals.<sup>101</sup>

To prepare carboxylic acids from aldehyde<sup>102</sup> or polyvinyl condensation products, the resins are heated with an excess of sodium hydroxide at a temperature sufficient to split off the maximum amount of hydrogen, extracted with water and the product precipitated with hydrochloric acid.<sup>103</sup>

## Chapter 53

### Polyacrylic Acid and Its Derivatives

Acrylic acid,  $\text{CH}_2=\text{CHCOOH}$ , is a colorless liquid which boils at  $141^\circ\text{C}$ . and has an odor like that of acetic acid. Structurally, this acid (as well as its derivatives such as the esters, nitrile, amide and acid chloride) has many points in common with vinyl alcohol and the esters described in the preceding chapters.<sup>1</sup> Acrylic acid is ethylene with one hydrogen atom replaced by the negative carboxyl group,  $-\text{COOH}$ . Like the vinyl esters, it polymerizes to a solid, which is believed to have the structure:

Polyacrylic acid would thus be classed as a polybasic acid. The esters of acrylic acid also undergo a change to yield solids that seem to have the structure:

Chemical differences between the hydrolytic products of polyvinyl esters and polyacrylic derivatives form the basis for describing them separately. Polyvinyl esters give polyvinyl alcohol as one of the products of hydrolysis. Polyacrylic acid derivatives<sup>2</sup> yield polyacrylic acid. Although ordinary polybasic acids are crystalline, polyacrylic acid is amorphous, as shown by x-ray examination.<sup>3</sup> Staudinger considers that the properties of polyvinyl alcohol are such as to class it with starch, but the properties of polyacrylic acid (especially its alkali salts) warrant its being considered an analogue of proteins.<sup>4</sup>

#### PREPARATION OF ACRYLIC ACID

General methods by which acrylic acid and related acids are obtained include: oxidation of the corresponding aldehyde or alcohol, dehydration of  $\beta$ -hydroxypropionic acid, and elimination of hydrogen halide or halogen from halogenated propionic acids.

Oxidation of acrolein by means of air or by shaking it with silver oxide was one of the early methods suggested.<sup>5</sup> The oxidation of this aldehyde in an organic solvent with air or oxygen is likewise feasible. For example, a 50 per cent solution of acrolein in benzene kept for 14 hours at  $50^\circ\text{C}$ . under oxygen at a pressure of 10 atmospheres gives a 73 per cent yield of the acid. When the reaction is stopped before more than about 80 per cent of the aldehyde has been oxidized,

<sup>1</sup> See Chapters 51 and 52. Compare also styrene (Chapter 11), another negatively substituted ethylene.

<sup>2</sup> According to H. Staudinger and E. Trommsdorff (*Ann.*, 1933, 502, 212; *Chem. Abs.*, 1933, 27, 4313), ethyl polyacrylate is more difficult to hydrolyse than is polyvinyl acetate.

<sup>3</sup> H. Staudinger and E. Urech, *Helv. Chim. Acta*, 1930, 12, 111; *Brit. Chem. Abs. A*, 1930, 64.

<sup>4</sup> Likewise, H. Staudinger considers that polystyrene (see Chapter 11) is structurally a molecular model for rubber and that polyethylene oxide (see Chapter 50) is a model for carbohydrates.

<sup>5</sup> Redtenbacher, *Ann.*, 1834, 47, 128.

polymerization of the acid is avoided.\* Oxidation of allyl alcohol yields acrylic acid along with other substances.<sup>7</sup>

When salts of hydracrylic acid<sup>8</sup> ( $\beta$ -hydroxypropionic acid) are heated (or when the acid itself<sup>9</sup> is distilled) dehydration to the unsaturated acid results. Van der Burg<sup>10</sup> formed acrylic acid by treating sodium hydracrylate (prepared by hydrolyzing ethylene cyanohydrin by means of a solution of caustic soda) with concentrated sulphuric acid.  $\beta$ -Chloropropionic acid decomposes when heated alone,<sup>11</sup> or with aqueous alkalis,<sup>12</sup> to give acrylic acid. Hydrochloric acid is also removed from  $\beta$ -chloropropionic acid or its esters by passing the vaporized acid or ester over a catalyst, e.g., active carbon, at 180-270°C.<sup>13</sup> Under similar conditions  $\alpha$ -bromopropionic acid yields some lactic acid as well.<sup>14</sup> Acrylic acid is obtained when  $\beta$ -iodopropionic acid is heated with alcoholic potash,<sup>15</sup> lead oxide<sup>16</sup> or sodium carbonate,<sup>17</sup> or when  $\alpha,\beta$ -dibromopropionic acid is treated with zinc<sup>18</sup> or other metals,<sup>19</sup> or when heated with aqueous potassium iodide solution.<sup>20</sup> In a similar manner, using high temperatures, acrylic acid may be produced from  $\alpha,\beta$ -dichloropropionic acid.<sup>21</sup>  $\alpha$ -Bromopropionaldehyde dimethyl acetal when shaken with lead hydroxide or moist silver oxide is another source of the acid.<sup>22</sup>

A proposed synthesis of acrylic acid from ethylene and carbon dioxide involves bringing the two gases into reaction at 200-300°C. in the presence of a catalyst. The latter may be an acid gas, a salt or an oxide, for example sulphur dioxide or sodium acid phosphate. Also a mixture of ethyl alcohol and carbon dioxide can be passed first over a dehydration catalyst to give ethylene and then over the catalyst for the formation of acrylic acid. The acid can be polymerized to a resin without its intermediate isolation.<sup>23</sup>

Hydrolysis of the nitrile of acrylic acid (vinyl cyanide) also gives acrylic acid. Baum and Herrmann<sup>24</sup> recovered vinyl cyanide after passing a mixture of acetylene and hydrogen cyanide over heated barium cyanide or activated charcoal.

### POLYMERIZATION OF ACRYLIC ACID

On standing, acrylic acid polymerizes<sup>25</sup> under the influence of light or heat and in the presence of a catalyst. As with vinyl acetate, the polymerization of both the acid and its esters by ultraviolet light is much slower in air or oxygen than in nitrogen or carbon dioxide. Staudinger and Kohlschütter<sup>26</sup> observed that

acrylic acid, illuminated in the presence of air or oxygen, underwent an especially rapid polymerization when, without discontinuing the illumination, the oxygen was displaced by carbon dioxide. Oxygen inhibits the photopolymerization not only of pure acrylic acid but also of its aqueous solutions. On the other hand, it accelerates the thermal polymerization. Addition of a small amount of hydroquinone prevents polymerization. Pure acrylic acid can be kept unchanged at ordinary temperature for a long time. On applying heat, partial polymer-formation takes place below 100°C. The temperature to which this acrylic acid polymerization product has been raised determines the readiness with which it can polymerize still further. Above 100°C. polymerization occurs rapidly and the heat of the reaction is such as to produce very high pressures when sealed tubes are used. The products obtained by polymerization of different preparations of acrylic acid vary in appearance, some being glassy and others, porcelain-like.

Polyacrylic acid is insoluble in the monomeric acid and separates as a solid phase during polymerization, instead of forming an increasingly viscous solution as in the case of vinyl acetate and styrene. In this respect it resembles polyvinyl halides. On the other hand, the polyacrylic esters are soluble in the monomers.

Catalysts like Florida earth have no influence on acrylic acid. Also, according to Staudinger and Urech,<sup>17</sup> stannic chloride, which is very effective with indene and styrene, does not polymerize acrylic acid. On adding it to the acid a violent reaction occurs but on decomposition of the complex which is formed, by means of water or alcohol, only the monomeric acid can be recovered. The stannic chloride compound is probably too stable to build up into large molecules.

The mechanism of the polymerization of acrylic acid is believed by Staudinger and Kohlschütter<sup>18</sup> to involve the activation of certain molecules through the agency of light or catalysts, and subsequent addition of other molecules to the activated molecules to form long chains. This addition of molecules continues until the energy of the original activated molecule has been dissipated. The growing chains initially have free end-valences but these eventually become stabilized by ring-formation or by other means of saturation such as combination with catalysts, solvent molecules or impurities that may be present.

That a chain reaction of many steps is the probable course is made plausible by the fact that monomeric acid can be distilled away from the polymerized material but there is no indication of low polymers such as the dimer or trimer. Low polymers of the latter class have been prepared from acrylic esters by means of condensing agents such as sodium methylate, but their mechanism of formation is to be ascribed to an entirely different process, namely, migration of a hydrogen atom from one molecule to saturate a double bond of a second molecule of ester. The means of polymerization which leads to unsaturated, low-molecular compounds is illustrated by the following equation:

This type of reaction may lead to slightly higher polymers having the structure:

<sup>17</sup> H. Staudinger and E. Urech, *Helv. Chim. Acta*, 1929, 12, 113; *Brit. Chem. Abs. A*, 1929, 64.

<sup>18</sup> H. Staudinger and H. W. Kohlschütter, *loc. cit.*

but it does not yield saturated polymers of high molecular weight. The formation of unsaturated low-molecular products in this way involves splitting one molecule and adding the H— and carboxy-vinyl residue to saturate another molecule, and so on. The products thus formed are so manifestly different from the saturated high-molecular polyacrylic acid of photo- or thermopolymerization that the conception of different mechanisms for their formation seems entirely justified.

Being completely saturated, polyacrylic acid shows no bromine absorption. It is also stable towards potassium permanganate and concentrated nitric acid. In contrast with polystyrene,<sup>20</sup> when heated above 300°C. it does not yield the monomer. Instead, pyrolytic products of the latter are obtained and in this respect it resembles the polyvinyl esters.

As with other polymeric products, a single molecular species is not formed by polymerization of acrylic acid or its derivatives, but a mixture consisting of molecules ranging in size from at least 100 monomeric units upwards, the average molecular size depending upon the conditions employed in the polymerization. Polyacrylic acid dissolves colloiddally in water and also in formamide. It is difficultly soluble in alcohol and insoluble in typical organic solvents like benzene, chloroform, acetone and acetic acid. The readiness with which it dissolves in water is dependent upon the way in which it is prepared. Only polymers prepared at a temperature above 120°C. dissolve easily. Those obtained at lower temperatures either yield exceedingly viscous solutions, or merely swell. Prepared at elevated temperatures, polyacrylic acid has a lower molecular weight than when prepared at low temperatures.

An aqueous solution of polyacrylic acid can be made by dissolving the water-soluble polymers. Also, since it is soluble in water, acrylic acid can be polymerized in this solvent to form a solution of the polymer. Hydrolysis of polyacrylonitrile in the presence of water also gives an aqueous solution of the polymerized acid. Neutralization of aqueous solutions of polyacrylic acid by means of alkalis forms soluble salts of the acid and greatly increases the viscosity. Sodium polyacrylate has been suggested as a dispersing and emulsifying agent for pastes of water-insoluble dyestuffs.<sup>21</sup> Color-lakes formed from acid dyes in the presence of an aqueous solution of sodium polyacrylate or other water-soluble products of high molecular weight, such as alkali salts of the co-polymers of acrylic acid and styrene, vinyl esters or vinyl ethers, have less covering power than ordinary lakes but are non-bronzing.<sup>22</sup> Acrylic acid has been mentioned as a constituent of a mixture which yields a synthetic rubber after polymerization and vulcanization.<sup>23</sup> Varnish constituents, germicides and dye compounds are formed by reacting polyacrylic acid with organic bases or their salts (e.g., quinine sulphate, nicotine, methylene blue). The co-polymers of styrene and maleic anhydride can be substituted for polyacrylic acid to obtain the same type of products.<sup>24</sup>

#### ESTERS OF ACRYLIC ACID

Kahlbaum<sup>25</sup> found that methyl acrylate, on long standing in the sunlight or when warmed, changed into a transparent, odorless mass of density 1.222, which decomposed when melted. It was insoluble in acids, alkalis, water, alcohol and ether, but swelled slightly in boiling acetic acid or benzene. When heated under reduced pressure a soluble liquid polymeric modification distilled (b.p. 190°C. at

<sup>20</sup> See Chapter 11.

<sup>24</sup> French P. 703,943, 1934, to I. G. Farbenind. A.-G.; *Chem. Abs.*, 1934, 28, 5190.

<sup>25</sup> G. W. A. Kahlbaum, *Ber.*, 1890, 13, 2343; 1895, 18, 2103.

100 mm.) which had an aromatic odor. Weger<sup>50</sup> noticed that when the methyl, ethyl or propyl esters of acrylic acid were distilled, they were partially converted into solids. Allyl acrylate polymerizes quite rapidly when exposed to sunlight.<sup>51</sup>

Although polyacrylic acid separates as a crust-like mass when the acid is allowed to polymerize in the light,<sup>52</sup> acrylic esters under the same conditions gradually increase in viscosity and pass from a viscous liquid to a glassy or rubber-like solid. Polyacrylic esters are soluble in the monomeric esters and in this respect are comparable with vinyl acetate and styrene. Polyacrylic esters also differ from the polymerized acid in solubility. They are insoluble in water and alcohol but dissolve in benzene, acetone and chloroform. The readiness with which they dissolve depends upon the extent to which the esters are polymerized. Only those polymerized at temperatures above about 120°C. dissolve freely; those obtained by polymerization at lower temperatures either merely swell or yield solutions of very high viscosity. However, if the temperature is increased sufficiently, not only will initially insoluble polymers gradually dissolve but also the viscosity of the more viscous solutions will be reduced. This is caused by the instability of the highest polymers at elevated temperatures and their tendency to break down into smaller, more soluble products.<sup>53</sup>

Staudinger and Trommsdorff<sup>54</sup> prepared a series of polymers of ethyl acrylate corresponding in degree of polymerization to from about 20 for the lowest polymers to more than 1700 for the highest. The lower polymers were obtained by dissolving ethyl acrylate in butyl acetate and heating the solution for varying periods. The highest was obtained from the pure ester by heating it at 100°C. for 12 days. Table 56 shows the molecular weight and the degree of polymerization; also the change in the properties of the different members of the series as the degree of polymerization increases:

TABLE 56.—Polymeric Modifications of Ethyl Acrylate.

No.	Molecular Weight	Degree of Polymerization	Properties of Polymers
1.	2200	22	A viscous, colorless oil. Dissolves easily in benzene. Solution of low viscosity.
2.	4000	40	Somewhat more viscous than 1.
3.	7800	78	Tough, somewhat fluid mass. Adheres to glass. Can be drawn out into threads.
4.	14500	145	Tougher than 3. Strong adhesion to glass. Can be drawn out into threads. Swells slightly in benzene, then dissolves.
5.	22500	225	Tougher than 4. Swells somewhat in benzene, then dissolves.
6.	41000	410	Very tough. Non-flowable. Difficultly drawn out into threads. Swells in benzene, then dissolves.
7.	175000	1750	Tough, elastic, rubber-like mass. Swells greatly in benzene, then dissolves giving solution of high viscosity.
8.	Too high to determine.		Very tough, elastic, rubber-like mass. Insoluble in benzene, but swells to 50 times its initial volume.

#### PREPARATION OF ACRYLIC ESTERS

Esters of acrylic acid are formed by esterification of acrylic acid or its functional derivatives. Also they can be formed in many of the same ways in which acrylic

<sup>50</sup> F. Weger, *Ann.*, 1888, 221, 86; *J.C.S.*, 1884, 46, 8.

<sup>51</sup> W. Caspary and B. Tollens, *Ann.*, 1873, 167, 241; *Chem. Zentr.*, 1873, 531.

<sup>52</sup> This is analogous to the polymerization of vinyl chloride under the influence of light. See Chapter 51. Compare also cuprene, Chapter 8.

<sup>53</sup> H. Staudinger and E. Urech, *Helv. Chim. Acta*, 1929, 12, 1128; *Brit. Chem. Abs. A*, 1930, 64.

<sup>54</sup> H. Staudinger and E. Trommsdorff, *Ann.*, 1933, 502, 207; *Chem. Abs.*, 1933, 27, 4213.

acid is produced, substituting an ester for the acid used in those reactions. The ethyl ester can be made by dissolving ethyl  $\alpha,\beta$ -dibromopropionate in alcohol and treating the solution with zinc and sulphuric acid<sup>40</sup> or with zinc alone.<sup>41</sup> The methyl ester of  $\alpha,\beta$ -dichloropropionic acid, dissolved in methyl alcohol and heated with zinc which has been activated by the addition of a small amount of mercury or a halogen, yields methyl acrylate.<sup>42</sup> Also,  $\beta$ -chloropropionic esters yield esters of acrylic acid when treated with alcoholic potash,<sup>43</sup> or when heated with a contact mass prepared by first impregnating active carbon with water glass, drying, and subsequently mixing with phosphoric acid and heating to 200°C.<sup>44</sup> An alternative method consists in distilling the  $\beta$ -chloropropionic ester with concentrated sulphuric acid to give a yield of 85-90 per cent of the desired ester.<sup>45</sup> Acrylic esters may also be synthesized by heating gradually to 160°C.,  $\beta$ -hydroxypropionitrile in an acid medium along with the appropriate alcohol and a dehydrating agent.<sup>46</sup> Ethylene cyanohydrin<sup>47</sup> (hydracrylonitrile) treated in alcoholic solution with concentrated sulphuric acid, and ethyl hydracrylate<sup>48</sup> heated at about 200°C. with phosphoric acid or with silica gel impregnated with sulphuric acid, are dehydrated to form acrylic esters.<sup>49</sup> Good yields of acrylic esters have been obtained by heating alcoholic solutions of the acid chloride with an acid-binding reagent.<sup>50</sup>

#### OTHER FUNCTIONAL DERIVATIVES OF ACRYLIC ACID

Acrylic acid nitrile,<sup>51</sup> chloride,<sup>52</sup> amide<sup>53</sup> and anilide<sup>54</sup> also polymerize. According to Staudinger and Urech,<sup>55</sup> the polymerized amide is an insoluble horn-like mass. In the polymerization of the amide by heat, ammonia is given off and an imide is partially formed. Ammonia can split out between adjacent  $\text{NH}_2$ -groups in the chain or between  $\text{NH}_2$ -groups in separate chains and leads to a linking of the chains and formation of an insoluble, 3-dimensional macromolecule instead of a linear molecule:

<sup>55</sup> H. Staudinger and E. Urech, *loc. cit.*

The anilide, when heated for 3 days at 130°C., changes to a dark brown, horn-like product which is insoluble in water and in all organic solvents. A similar material results from heating polyacrylic acid chloride with aniline. The nitrile can be polymerized by emulsifying it with water and heating it to 100°C. with the addition of hydrogen peroxide. Polymerized acrylonitrile may be saponified to give polymeric acids from which the corresponding polyacrylic esters are derived.<sup>66</sup> Resinous products were obtained when Auwers and Ungemach<sup>67</sup> attempted to condense the nitrile with diazomethane. By heating acrylic acid chloride to 150°C. it polymerizes to a brown insoluble mass. Bases such as triethylene-tetramine or biperidyl serve as catalysts. Under the influence of ultraviolet light at ordinary temperatures an almost colorless, glassy product is obtained, which also is insoluble in all solvents. When polyacrylic acid is treated with phosphorus trichloride or thionyl chloride, the same type of insoluble product is obtained.

Soluble resins that were suggested for use with nitrocellulose in lacquers are obtained by treating the polymers of acrylic acid chloride or nitrile under pressure at 35-150°C. with substances capable of reacting with the Cl- or CN group. Water reacts to form polyacrylic acid, or with less than an equivalent amount of water present to form polyacrylic anhydride. Aqueous solutions of alkalies give salts of polyacrylic acid. Ammonia, primary and secondary amines form the polyamide and substituted polyamides. Other reactants which can be used are alcohols, hydrogen sulphide, mercaptans, or malonic and acetoacetic esters. Also co-polymers of acrylic acid chloride or nitrile with vinyl acetate, acrylic esters or styrene can be treated in the same way.<sup>68</sup> A solution of sodium polyacrylate, obtained by hydrolysis of polymerized acrylonitrile by means of sodium hydroxide solution, is recommended as a dispersion agent for preparation of pastes of water-insoluble dyestuffs for printing or as an emulsifying agent for oil-water emulsions.<sup>69</sup>

#### POLYMERIZATION OF ACRYLIC ACID DERIVATIVES

Acrylic acid and its derivatives can be polymerized by heating them in the presence of oxygen or organic peroxides. A solvent such as acetone may be present.<sup>60</sup> Also mixtures of acrylic acid derivatives with other polymerizable substances can be subjected to light or heat in the presence of a polymerization catalyst to yield co-polymers. For example, a mixture of ethyl acrylate with vinyl acetate may be polymerized,<sup>61</sup> or a mixture of acrylic acid, its esters or nitrile with styrene.<sup>62</sup> The co-polymerization of acrylic and vinyl esters results in the formation of products hydrolyzable to lactones when treated with strong acids.<sup>63</sup> In general,

<sup>65</sup> French P. 697,693, 1930, to I. G. Farbenind. A.-G.; *Chem. Abs.*, 1931, 25, 3136.

<sup>66</sup> British P. 371,896, 1930, to I. G. Farbenind. A.-G.; *Brit. Chem. Abs. B.*, 1932, 688. See also French P. 715,961, 1931; *Chem. Abs.*, 1932, 26, 2653.

<sup>67</sup> French P. 765,272, 1934, to I. G. Farbenind. A.-G.; *Chem. Abs.*, 1934, 28, 6956. British P. 416,885, 1934; *Chem. Abs.*, 1935, 29, 1181.

co-polymers are insoluble in water and are recommended for forming threads, coatings or binding agents. Furthermore, acrylic acid derivatives can be polymerized in mixture with butadiene. Thus, a mixture of butadiene and acrylonitrile<sup>66a</sup> or acrylic esters<sup>66</sup> is heated and the co-polymers, after being milled with lamp-black, can be vulcanized to form rubber-like masses. Molded objects resembling celluloid are obtained by working, in the manner used for manufacture of celluloid, the co-polymers formed with vinyl chloride, acrylonitrile, acrylic acid, styrene or  $\beta$ -chlorobutadiene in mixture with acrylic esters, vinyl ethers or alkyl vinyl ketones.<sup>67</sup> A proportion of at least 20 per cent acrylic acid nitrile in the co-polymerization product mixture is stated to be advantageous.<sup>68</sup> The polymerization of these compounds may be carried out in a paraffin oil solution, and since the polymers, so formed, are insoluble in this solvent the recovery of the resinous products is facilitated.<sup>67</sup> Acrylic acid derivatives can also be polymerized with maleic anhydride to form heteropolymers.<sup>69</sup>

Emulsions of acrylic esters containing a polymerization catalyst can be heated or exposed to light and the polymer afterwards separated. For example, methyl acrylate, emulsified with water containing sodium isopropyl-naphthalenesulphonate and hydrogen peroxide, and heated to 70-90°C., yields a latex which can be precipitated by addition of hydrochloric acid. This product can be formed into rubber-like threads or films. Other polymerizable substances such as styrene, acrylic acid, acrylonitrile, butyl methacrylate or vinyl acetate can be mixed with the acrylic ester before polymerization,<sup>70</sup> and the resulting aqueous dispersions may be used as adhesives.<sup>70</sup> Another polymerization process for methyl acrylate consists in emulsifying the ester in water with sulphonated castor oil as emulsifying agent and heating in a closed vessel with 1 per cent of a peroxide catalyst. As soon as the desired degree of polymerization is reached the reaction is terminated by addition of cold water. This makes the reaction controllable even in large-scale operations. Vinyl acetate may be mixed with the acrylic ester and a co-polymer of the two obtained in this way.<sup>71</sup> Co-polymers of acrylic acid derivatives and vinyl ethers are also formed by emulsifying the mixture and subjecting the emulsion to one of the above treatments. Vinyl ethyl or butyl ether, or glycol vinyl ethyl ether can be mixed with acrylonitrile or methyl acrylate to give products that range from rubber-like to celluloid-like masses.<sup>72</sup>

Dykstra<sup>73</sup> polymerized esters of other unsaturated acids (maleic or fumaric acids and their homologues) with the aid of heat and actinic light. Catalysts such as benzoyl peroxide and triethyl-lead acetate may be used to advantage in this reaction, and the resins, so obtained, are said to be useful in the preparation of lacquers.

## USES OF POLYACRYLIC ACID DERIVATIVES

By evaporation of thin layers of solutions of polymerized acrylic esters, tough, clear films are formed which are water-resistant and durable. Röhm<sup>74</sup> proposed the use of such solutions as coating compositions, or for impregnating wood and fabrics. As solvents he used acetone or ethyl acetate. When exposed to ultra-violet light the films are hardened. Coating compositions can also be made by dissolving the unpolymerized esters in a solvent and carrying out the polymerization reaction in solution. Another coating composition consists of cellulose ethers mixed with polyacrylic esters, using an aqueous solution of water-soluble alkyl cellulose and an emulsion of the polymerized ester.<sup>75</sup>

A 10 per cent solution of ethyl polyacrylate in acetone is recommended as an adhesive for sticking paper or fabrics to metal.<sup>76</sup> As the cementing and supporting layer for laminated glass,<sup>77</sup> polyacrylic esters seem promising on account of their adhesion and rubbery nature, which lends non-splintering qualities to glass.<sup>78</sup> Giesel<sup>79</sup> has suggested the employment of ethyl or methyl polyacrylate for this purpose.<sup>80</sup> Cellophane or cellulose acetate coated with a polyacrylic ester yields non-brittle, transparent, binding sheets for shatterproof glass.<sup>81</sup> Methods for making compound glass have been described<sup>82</sup> in which the adhesive agent is prepared by polymerizing mixtures of unsaturated compounds containing derivatives of acrylic acid. For example, an adhesive for this purpose can be produced by polymerizing a mixture of methyl acrylate, vinyl cyanide and isoprene. The condensation product formed by the reaction between maleic anhydride and castor oil or 1,3-butylene glycol can be mixed with polyacrylic esters and serve to increase the adhesion to glass and to make the polymers less brittle when cold.<sup>83</sup> Copolymers of vinyl esters and acrylic esters have also been proposed for the supporting layer between glass plates.<sup>84</sup> These ester polymers are likewise used for attaching metal, textile, glass or leather surfaces to one another.<sup>85</sup> Their elasticity, insolubility in oil and water and light-resistance enhance their utility in making shatter-

proof glass.<sup>86</sup> Mixed with such resins as toluenesulphonamide-formaldehyde, polyacrylic esters are stable towards light and are plastic at low temperatures.<sup>87</sup>

A sheet of polyacrylic ester can be used alone as a glass substitute.<sup>88</sup> However, plasticizers such as phthalic esters or monacetin may be added to increase the viscosity and to make the layer tougher.<sup>89</sup> The sheet can also be strengthened by supporting it on a metal screen. For example, wire gauze is dipped into a concentrated solution of the polymer, lifted out and allowed to drain.<sup>90</sup>

Röhm<sup>91</sup> proposed a rubber substitute, made by heating a polymerized acrylic ester with sulphur. As a material for floor coverings or as a leather substitute, derivatives of polyacrylic acid are mixed with fillers (cork dust, talc and carbon black) and softeners.<sup>92</sup> Films and other colloidal products of high degree of polymerization acquire undesirable electric charges which are said to be reduced by including, during the preparation, polymeric carboxylic acids or their salts. A proposed resin of this kind consists of a mixture of polyacrylic acid and polyvinyl chloride, films of which may be formed from dichloromethane solution.<sup>93</sup> Insulation for wires or cables consists of polymerized acrylic acid, its esters, acid chloride or nitrile, together with paper, mica and linexyn.<sup>94</sup> Sheets impermeable to gases and suitable for gas-masks are made by pressing together alternate layers of leather, cloth or paper, and a film about 0.5 mm. thick of ethyl polyacrylate or polyvinyl acetate.<sup>95</sup>

Derivatives of polyacrylic acid possess characteristics favorable to the production of molding compositions and other artificial masses. Plastic materials may be formed by treating a chloroform solution of acrylic acid esters with chlorine in the presence of sunlight.<sup>96</sup> This method is said to impart improved mechanical properties to the product as well as to increase the softening point and resistance to solvents. A white porous mass was obtained from a chloroform solution of polymerized methyl acrylate by treating with chlorine, removing the resultant hydrochloric acid and blowing in steam. The product may be mixed with linseed oil to give a plastic material.<sup>97</sup> A mixture of methyl acrylate and vinyl acetate polymerized by heat, electrical energy or light in the presence of the usual catalysts yields a resin which may be molded.<sup>98</sup> The metallic (e.g., silver, mercuric, ferric, nickel, cobalt) polyacrylates and polymethacrylates are said to possess useful thermoplastic and film-forming properties.<sup>99</sup> Masses to be employed in making sound records are produced by kneading an iron powder with polyacrylic compounds until the agglomerated particles of metal are broken down to 6-8  $\mu$ .<sup>100</sup>

In addition to molded articles, polyacrylic acid derivatives have found application in preparing lacquers, varnishes and other coating compositions. Acrylic

acid forms an active constituent in a polymerization mixture of vinyl compounds, the products of which may be used in making lacquers.<sup>102</sup> Aqueous dispersions said to be useful for coating and impregnating leather, wood, paper and textiles<sup>103</sup> are prepared by polymerizing an aqueous emulsion of methyl acrylate with hydrogen peroxide at 70-95°C. with the addition of a small amount of Turkey-red oil and sodium di-isopropyl-naphthalenesulphonate. Products applicable to a variety of uses result when acrylic esters are polymerized with styrene in the presence of a non-solvent liquid and a peroxide polymerization catalyst.<sup>104</sup> For example, a mixture of styrene and butyl acrylate along with toluene and benzoyl peroxide polymerizes to yield a viscous solution which may be utilized without further treatment for coating purposes or for the preparation of lacquers. Mixed polymerization products of vinyl ethers with acrylic esters, amides, anilides or nitriles have found use as binding agents and in the manufacture of varnishes and lacquers. Also in admixture with fillers, fabrics and pigment, substitutes for oilcloth, leather and linoleum may be produced.<sup>104</sup>

Printing inks<sup>105</sup> have been described in which a water-soluble coloring matter is added to an aqueous dispersion of amorphous polymers. A typical ink consists of Diamond Green G, glycerol, thioglycol, alcohol, starch and the sodium salt of polyacrylic acid.

Polymerized acrylic esters are stated to render fabrics impermeable to gases, thus producing a useful material for the manufacture of gas masks.<sup>106</sup> Synthetic resins of practical importance have been produced by condensing polyacrylic acid with organic hydroxy compounds.<sup>107</sup> Waterproofing of fibrous materials is said to be accomplished by immersing the cloth in a solution of the ammonium salt of polyacrylic acid and subsequently treating the fabric with a solution of aluminum acetate to form an insoluble salt of the polymer.<sup>108</sup> Water-soluble salts of polyacrylic acid may also find use in the preparation of photographic films.<sup>109</sup>

#### HALOGEN SUBSTITUTION PRODUCTS OF ACRYLIC ACID

Monobromo derivatives of acrylic acid may be obtained from  $\alpha$ - and  $\beta$ -dibromopropionic acids by elimination of a molecule of hydrogen bromide.  $\alpha$ -Monobromoacrylic acid may be so prepared by subjecting  $\alpha$ -dibromopropionic acid to treatment with alcoholic potash with subsequent addition of sulphuric acid to liberate the free acid. The product slowly loses hydrogen bromide on standing to give a soft brownish mass.<sup>110</sup> In a similar manner,  $\beta$ -bromoacrylic acid may be derived from the corresponding  $\beta$ -dibromopropionic acid.<sup>111</sup>

Wagner and Tollens<sup>112</sup> observed that a yellow gelatinous substance was obtained when  $\beta$ -bromoacrylic acid was heated with alcoholic potash. The dried product is insoluble in alcohol, ether and water, although a pronounced swelling of the

<sup>113</sup> R. Wagner and B. Tollens, *Ann.*, 1874, 171, 355; *J.C.S.*, 1874, 27, 681. M. Garino and G. Bornate (*Gazz. chim. ital.*, 1927, 57, 380; *Chem. Abs.*, 1927, 21, 3600) obtained a pitch when an alcoholic solution of chlorobromopyruvic acid and cinchonine was evaporated.

resinous material takes place in the solvents. Saturation was indicated by the failure of the material to react with bromine or iodine. Complete solution was obtained by using ammonium hydroxide, from which the mass could not be precipitated by the addition of mineral acids. A somewhat similar porous product was obtained by allowing  $\beta$ -bromoacrylic acid to stand over concentrated sulphuric acid. However, the latter polymer differed from the first in that it could be precipitated from its ammoniacal solutions. A third polymeric substance, obtained by treating the potassium salt of the  $\beta$ -bromoacrylic acid with ethyl bromide, was insoluble in ammonium hydroxide. In all three instances, analysis indicated the polymeric formula,  $(C_3H_3O)_n$ .<sup>118</sup>

#### PREPARATION AND POLYMERIZATION OF METHACRYLIC ACID

Lossen and Gerlach<sup>114</sup> used as a starting material for the synthesis of methacrylic acid ( $\alpha$ -methylacrylic acid),  $\alpha$ -bromoisobutyric acid. A yield of 8 per cent of the acid was obtained by splitting off hydrogen bromide with water, 14.8 per cent with 1 *N* sodium hydroxide solution at 80°C., and 75 per cent with 25 per cent alkali. On the other hand,  $\beta$ -bromoisobutyric acid yields only methacrylic acid under all of the foregoing conditions. Methacrylic acid may also be prepared by dehydrating  $\alpha$ -hydroxybutyric acid with phosphorus pentoxide.<sup>115</sup> Crawford<sup>116</sup> synthesized methacrylic acid by heating acetone cyanohydrin in concentrated sulphuric acid at 100-110°C. Polymerization is prevented by the addition of sulphur or diphenylamine.

Methacrylic acid is very susceptible to polymerization.<sup>117</sup> It undergoes polymerization upon distillation, long standing, addition of a few drops of acid or when its aqueous solutions are heated at 130°C. The product obtained in the latter instance is a white porcelain-like mass, insoluble in all neutral solvents. A marked swelling similar to that of gums and starches takes place when the polymer is added to water. The polymerization product is a weak acid which may be dissolved in ammonium hydroxide and reprecipitated with hydrochloric acid. Gummy masses result when its ammoniacal solutions are treated with barium or calcium chloride. According to Mjöen,<sup>118</sup> polymethacrylic acid begins to decompose at 200°C. and volatilizes at 300°C. without melting. Moreover, the polymer is quite resistant to oxidation, being unaffected by potassium permanganate or chromic acid. Titration of this weakly acidic substance with barium hydroxide solution indicates that it is an octabasic acid and in view of the molecular weight estimations, the formula  $(C_4H_5O)_x$  has been proposed, where *x* has a value in the neighborhood of 8.

The zinc and lead salts of methacrylic acid polymerize readily upon heating.<sup>119</sup> The esters of alkylated acrylic acids have been used as sources of resinous products.<sup>120</sup> For example, Fleming and Renfrew<sup>121</sup> used methyl methacrylate and

<sup>112</sup> W. Lossen and E. Kowaki (*Ann.*, 1905, 342, 133; *J.C.S.*, 1906, 90 (1), 59) consider this substance to be polymerized pyruvic acid, since a syrup obtained by extracting an alkaline solution of the polymer with ether combined with phenylhydrazine to give the phenylhydrazone of pyruvic acid.

products obtained by polymerizing mixtures of methyl acrylate and ethyl methacrylate in the manufacture of an adhesive to be used in the production of laminated glass. Plastic products of commercial significance may be obtained by polymerizing methyl methacrylate by exposure to light and heat, using an organic peroxide or ozonide as a catalyst.<sup>122</sup> In this manner a thermoplastic resin has been prepared which softens only above 100°C. and can set within a small temperature range from a moldable to a rigid, solid condition.<sup>123</sup> Plasticizing agents, fillers and insoluble coloring matter are milled with the acrylic acid derivatives prior to polymerization. The resulting polymer is powdered and molded under pressure (200 pounds per square inch) at 80-200°C. The ethyl ester of methyl acrylic acid, also, yields plastic resins under somewhat similar conditions.<sup>124</sup> In one instance the polymerization is carried out by means of heat or light and with the aid of a benzoyl peroxide catalyst. The resulting polymers are softened by the addition of dibutyl tartrate and dissolved in ethyl acetate. Evaporation of the solvent leaves a film of such character as to recommend it as a boiler-lining or for protective coatings in general.

Before painting rubber surfaces, Münzinger<sup>125</sup> suggests applying an intermediate coating of a polymethacrylic ester in benzene solution (containing a softening agent and rubber). When methacrylonitrile is polymerized alone or with such substances as methyl methacrylate, bubble-formation or distortion due to contraction on cooling is obviated by using a vessel provisionally prepared with a flexible rubber or metal-foil lining.<sup>126</sup>

#### RESINOUS PRODUCTS FROM CROTONIC ACID DERIVATIVES

Crotonic acid ( $\beta$ -methylacrylic acid) does not polymerize as readily as methacrylic acid to give resins,<sup>127</sup> but its esters and other derivatives form useful polymers. Schmidt<sup>128</sup> reports that the polymers of crotonic acid have been obtained in varying degrees of hardness. They are colorless, light-stable and compatible with natural and synthetic resins, plasticizers and most cellulose esters and ethers. Crotyl cellulose in combination with a drying agent may be used in the preparation of lacquers.<sup>129</sup> The film of crotyl cellulose may be polymerized by baking or by exposure to ultraviolet light. Cellulose crotyl esters readily polymerize and have been recommended for use in the manufacture of lacquers, coating compositions, plastic masses, artificial filaments and splinterless glass.<sup>130</sup> Fordyce<sup>131</sup> produced a sheet of solvent-resistant material by treating cellulose tricotinate for 5 hours with intense ultraviolet light or heating at 100°C. for 24 hours. Crotonic acid undergoes condensation and subsequent polymerization when treated with olefins at a temperature of 160°C. Synthetic resins of varied usefulness are said to be produced in this manner.<sup>132</sup> Glycerol can be esterified wholly or partially with crotonic acid to give products which have been added to resins, gums and

waxes to modify their properties. The crotonic-glycerol esters may also replace camphor in nitrocellulose plastics.<sup>128</sup>

Skraup and Beng<sup>124</sup> have reported that the phenyl ester of  $\beta$ -methylcrotonic acid resinifies on heating at a temperature of 320-330°C. Certain vinylene homologues of crotonic acid esters have been observed to undergo polymerization. Thus Kuhn and Hoffer<sup>129</sup> found that the methyl ester of 2,4,6-octatrienic acid polymerized on long standing to a viscous, yellow, gum-like mass. Also, methyl 3-hydroxy-3-methyl-4,6-octadienate autoxidizes in air to give a viscous syrup. A similar product was obtained from the methyl ester of  $\beta$ -methyloctatrienic acid.

#### POLYMERIZATION OF CINNAMIC ACID AND RELATED COMPOUNDS

Cinnamic acid ( $\beta$ -phenylacrylic acid) exists in two isomeric forms, namely,

The trans-configuration has been assigned to ordinary cinnamic acid. Long ultra-violet rays (e.g., sunlight) favor polymerization whereas shorter rays (mercury arc ray) hinder it. In general the irradiation of cinnamic acids results in isomerization rather than polymerization, and when polymerization does take place, it usually stops at the formation of saturated dimers.<sup>130</sup> However, Stobbe and Lehfelddt<sup>137</sup> reported that nearly a 60 per cent yield of resin was obtained when  $\beta$ -trans-cinnamic acid was subjected to winter sunlight for 5 months. Also, after 4 weeks exposure to summer sunshine, 20 per cent of resinous material was found present.<sup>138</sup>

The esters of cinnamic acid are more prone to polymerization than the acid itself. Liebermann and Zsuffa<sup>139</sup> examined the polymerization tendencies of the methyl, ethyl, isoamyl, benzyl and allyl esters of cinnamic acid by exposing the esters to the influence of ultraviolet light or sunlight. The ethyl ester was found to polymerize most readily followed by the isoamyl ester. However, in general the yields were quite low, being only from 3 to 6 per cent in the case of ethyl cinnamate. Favorable conditions for polymerization involved distillation of the ester, followed by exposure to light for a long period of time with subsequent heat treatment at 85-90°C. for 10-20 hours. The products as obtained were white, infusible, odorless and sparingly soluble. A study of the properties of the polyesters indicated a trimer of the possible constitution

On the other hand, when polymerization is carried out by special heat treatment alone, different types of polymers are obtained.<sup>140</sup> Heat polymerization of allyl cinnamate yields two different polymers, depending upon the reaction time. Polymer A was obtained in 25 per cent yield when the ester was heated in a sealed tube at 210°C. for 6 hours; a 60 per cent yield of polymer B resulted when the heating time was extended to 15 hours. The heat-polymers differ in several respects from the corresponding light-polymers. For example, the heat-polymers may be hydrolyzed with 40 per cent aqueous alkali or 25 per cent alcoholic alkali, whereas the light-polymers are quite resistant to hydrolysis. The following structure has been assigned to the heat-polymer of allyl cinnamate:

Polymerized methyl cinnamate is recommended as an adhesive material for the preparation of unsplinterable glass.<sup>141</sup> The polymerization is effected by either heat or light. According to Ostromislensky<sup>142</sup> the polymerized esters of phenylacrylic acid are particularly adaptable for the manufacture of non-shattering glass because of their permanent clear, colorless transparency and their high refractive indices. Amyl, amylene, isopropyl, butylene and isobutylene esters of phenylacrylic acid may be polymerized by heat or exposure to ultraviolet light. Chlorobenzene, ethylene bromide or similar solvents have been used in preparing adhesives. The ethyl and methyl esters are also said to be effective when used in conjunction with cellulose esters.<sup>143</sup> An amber-colored varnish resin may be prepared by heating allyl cinnamate for 36 hours at 170°C. in a closed enamelled vessel, after which the temperature is raised to 230°C. and maintained for an additional 36 hours.<sup>144</sup> Skraup and Beng<sup>145</sup> have reported that the phenyl ester of cinnamic acid shows evidence of considerable resinification when heated in a sealed tube for 25 hours at 290-300°C.

Cinnamalacetic acid  $\text{C}_6\text{H}_5\text{—CH=CH—CH=CH—COOH}$ , according to Liebermann and Riiber,<sup>146</sup> yields liquid polymeric modifications of phenylbutadiene when heated with barium hydroxide. Blicke<sup>147</sup> polymerized the allyl ester of cinnamalacetic acid by heating it in a sealed tube at 210°C. for 7 days. At the end of this time the solid, light-yellow, transparent mass was dissolved in warm acetone, filtered and cooled to 0°C. The polymer was isolated by pouring the acetone solution into a large volume of cold alcohol. The purified polymeric ester was obtained in 25 per cent yield as an amorphous, amber-like solid. A small yield of a white, gummy substance was obtained with this ester upon exposure to sunlight for several days. The nature of the product was not investigated, but it is believed to be analogous to the light-polymers obtained by Liebermann<sup>148</sup> and

his co-workers. Clemo, Haworth and Walton<sup>140</sup> found that  $\beta$ -4-methoxy-2,5-dimethylbenzoylacrylic acid was converted into a tarry mass when heated to 100°C. Also another substituted acrylic acid, 3,5-dimethyl-4-carbethoxy-pyrrol-2-acrylic acid, was obtained in the form of a resinous dark brown, glassy mass upon heating to 200°C.<sup>140</sup> The product is insoluble in ether, but dissolves readily in alcohol and acetone.

Atropic acid ( $\alpha$ -phenylacrylic acid) also seems to be capable of exhibiting cis-trans isomerism.<sup>151</sup> Dimers, bearing the same relation to atropic acid as the truxillic acids do to cinnamic acid, were obtained by protracted fusion or heating aqueous solutions. Possible constitutional formulas for the two isotropic acids were proposed by Fittig.<sup>152</sup>

Baker and Eccles<sup>153</sup> observed that the methyl ester of atropic acid polymerized after standing.

#### VINYLACRYLIC ACID AND ITS DERIVATIVES

Polymeric modifications of  $\beta$ -vinylacrylic acid were observed by Doebner<sup>154</sup> to form slowly when the acid was allowed to stand at room temperature. However, the transformation took place rapidly when the acid was heated at 130°C., yielding an amorphous, brittle product of the formula  $(C_5H_6O_2)_x$ . The polymer is insoluble in organic solvents with the exception of acetic acid, in which solution occurs with difficulty at the boiling temperature. The resin may be dissolved by heating in a sodium hydroxide solution; however, solutions of sodium carbonate have very little solvent action. Decomposition of the polymer takes place at 300°C. A white, rubber-like polymer was prepared by Burton and Ingold<sup>155</sup> during the crystallization of crude vinylacrylic acid from water between 55° and 15°C. The yield of polymer thus obtained increased with the time of crystallization. The fact that esters of vinylacrylic acid readily absorb oxygen from the air to form tough films has suggested their use as a substitute for linseed oil.<sup>156</sup>

Halogen-substitution products of vinylacrylic acid are relatively unstable and undergo polymerization quite easily. Muscat and Becker<sup>157</sup> have reported that a sharp melting point for chlorovinylacrylic acid is not obtainable because of its ready polymerization. The polymer obtained from this acid is a light yellow solid, soluble in acetone, but insoluble in other ordinary organic solvents. Simi-

larly, monobromovinylacrylic acid is very susceptible to polymerization.<sup>158</sup> When this substance was heated it changed without melting or evident degradation to a yellow, apparently amorphous solid, which gradually darkened in color as the temperature rose. Bromovinylacrylic acid cannot be kept, since it invariably goes over to a brown, amorphous mass in less than 2 days. The methyl ester of bromovinylacrylic acid polymerizes to a thick jelly on standing for two hours at room temperature.<sup>159</sup> Muscat and Hudson<sup>160</sup> obtained what appeared to be a polymer of 3-chlorovinylacrylic acid by shaking an ethereal solution of vinylacrylic acid chlorohydrin with phosphorus pentoxide.

#### RESINOUS POLYMERS FROM ESTERS OF ITACONIC ACID

Itaconic acid  $\text{CH}_2=\text{C}-\underset{\text{COOH}}{\text{CH}_2}-\text{COOH}$  has found little or no use as a source of

resinous polymers.<sup>161</sup> However, its esters yield various products upon polymerization, some of which are of special technical significance. In general, earlier investigators have reported the polymerization of dialkyl esters of itaconic acid to be quite slow. Swartz<sup>162</sup> observed that diethyl itaconate was converted, on long standing, to a solid, glass-like modification. Anschütz<sup>163</sup> prepared a similar product by allowing the sample of itaconic ester to stand for 19 months (in order to ensure complete polymerization). The slowness of these reactions was also confirmed by Fittig and Bock,<sup>164</sup> who found, in addition, that polymerization did not occur at all in the presence of ethyl alcohol. Amyl itaconate also undergoes polymerization to yield a glass-like polymer.<sup>165</sup>

A thorough investigation of the effect of light on the polymerization of ethyl itaconate was carried out by Stobbe and Lippold.<sup>166</sup> The course of the polymerization was followed by periodic measurements of the refractive index. The pure ester, whose index of refraction was 1.43609, was converted after 65 days of exposure to sunlight into an amorphous polymer, giving the crude mixture a refractive index of 1.44928. Light seems to be an essential factor in the conversion, for a similar preparation in the dark remained unchanged. In addition to the light, traces of hydrogen chloride were said to increase the rate of reaction. The polymer, as obtained, is an odorless, colorless, glassy substance which dissolves in the monomeric ester to form a viscous liquid. The polymer cannot be distilled, since even *in vacuo* it decomposes, yielding volatile products.

Extensive experiments dealing with the conditions of polymerization have enabled Hope<sup>167</sup> to produce desirable polymers without recourse to light-exposure. Provided anticatalytic phenomena were avoided, it was found possible to accelerate the reaction to a marked extent by heating. The polymerized ester has found application in the manufacture of laminated glass. A partially polymerized paste is applied to a sheet of cellulose acetate, which is then placed

between two sheets of glass and heated for 3 days at 70°C. to complete the polymerization. Vitreous masses which may be molded are obtained in a similar manner.

Polymerized itaconic acid has been recommended as a constituent of modified resins. When mixed with a urea-formaldehyde condensation product, resins said to be useful in the manufacture of varnishes, films, artificial silk and molded articles have been obtained.<sup>168</sup> Jaeger<sup>169</sup> has described a resinous product (which can be molded and polished), obtained by adding polymerized itaconic acid to a phthalide-modified alkyd resin.<sup>170</sup> Media for the dispersing of insoluble substances can be made from derivatives of polymeric itaconic acid mixed with complex polymerization products obtained by simultaneous condensation and polymerization of vinyl compounds.<sup>171</sup> When dissolved in water, either alone or mixed with starch, dextrin or gum arabic, the viscous masses may be used for dispersing dyes or pigments. The viscous preparation may also be employed in the manufacture of printing pastes, printing inks, coating preparations and colloidal pastes of coloring materials.

The polymers of itaconic acid and its esters (as well as acrylic acid and its esters, vinyl alcohol esters and ethers, and styrene) have been suggested as material for the manufacture of phonograph records.<sup>172</sup>

## Chapter 54

### Resins from Rubber

#### I. General Considerations

##### STRUCTURE OF RUBBER

Mention has already been made of the very intimate relationship existing between resins and rubber-like substances.<sup>1</sup> Heat and certain chemical reagents convert rubber into resinous bodies. The exact formulation of the changes which take place is not known, but fairly definite concepts as to the transformations involved may be based on the assumed structure of rubber.

Rubber<sup>2</sup> is an emulsoid consisting of the colloidal hydrocarbon rubber in a fine state of subdivision; the rubber not only forms the disperse phase but also its own dispersion medium. The impurities in crude rubber consist of resins, proteins, carbohydrates and enzymes and may be removed if necessary by dissolving the rubber in an appropriate solvent and precipitating.<sup>3</sup> As is the case with most gels, there is first a swelling of the rubber and absorption of the solvent resulting in a colloidal solution of high viscosity.<sup>4</sup>

The purified rubber reveals on analysis the empirical formula,  $C_5H_8$ . The general properties indicate a much more complex molecule. The structure of rubber is based on the following considerations: 1, the close relationship between isoprene and rubber; 2, the decomposition products of rubber ozonides; and 3, the formation of addition compounds.

Of the changes which rubber undergoes, the most instructive, at least from the historical point of view, are those arising from destructive distillation. A systematic study of the distillation products was very early undertaken by Bouchardat<sup>5</sup> and later by Williams.<sup>6</sup> The latter obtained a liquid (boiling at 37°C.) having the formula,  $C_5H_8$ , to which he gave the name "isoprene." Before any elucidation of the structure of rubber might arise, it was necessary to know the constitution of isoprene. Tilden,<sup>7</sup> on purely empirical grounds considered it to be 2-methyl butadiene and the correctness of this contention was established by Kondakov,<sup>8</sup> by Ipatiev and Wittorf<sup>9</sup> and by Euler.<sup>10</sup>

Dipentene was also found in the products of the destructive distillation of rubber and its mode of formation is readily explained by a simple union of two isoprene molecules

<sup>1</sup> See Chapters 4 and 9.

<sup>2</sup> For an extensive discussion of rubber, its sources, structure, physical properties and chemical transformations, see K. Memmler, "The Science of Rubber," trans. by R. F. Dunbrook and V. N. Morris, Reinhold Publishing Corp., New York, 1934.

<sup>3</sup> F. Heim and R. Marquis, *Bull. de l'Office Colonial*, 1915, 8 (86), 101; *J.S.C.I.*, 1915, 34, 1062.

<sup>4</sup> The colloidal changes involved in vulcanisation and the action of copper salts on raw rubber have been discussed by I. Williams (*Ind. Eng. Chem.*, 1934, 26, 1190) and by B. V. Buisov, V. S. Molodenakii and N. I. Mikhailov (*Kautschuk*, 1934, 10, 86, 104; *Chem. Abs.*, 1934, 28, 6589) respectively.

<sup>5</sup> A. Bouchardat, *J. de Pharmacie*, 1837, 23, 457.

<sup>6</sup> G. Williams, *Proc. Roy. Soc.*, 1880, 10, 516.

<sup>7</sup> W. A. Tilden, *Chem. News*, 1883, 46, 120; *J.C.S.*, 1883, 44, 75.

<sup>8</sup> I. Kondakov, *J. Russ. Chem. Soc.*, 1883, 20, 706; 1889, 21, 80; *J.C.S.*, 1889, 56, 1127.

<sup>9</sup> W. Ipatiev and N. von Wittorf, *J. prakt. Chem.*, 1897, (3) 53, 1; *J.C.S.*, 1897, 72 (1), 233.

<sup>10</sup> W. Euler, *Ber.*, 1897, 30, 1989.

Although dipentene is the chief product in the distillation of rubber, opinion is divided as to whether it arises from a primary or secondary process, that is from rubber or from isoprene.

Further evidence regarding the structure of rubber came from ozonolysis. When ozone is passed into a chloroform solution of rubber, an ozonide is formed which can be isolated as a vitreous mass and purified by solution in ethyl acetate and subsequent precipitation with petroleum ether. Analysis of the ozonide revealed the composition  $(C_5H_8O_3)_x$ , further evidence for a double bond for each 5-carbon moiety.<sup>11</sup> When heated with water the ozonide decomposed into hydrogen peroxide, levulinic aldehyde and levulinic aldehyde peroxide, which in turn further decomposed into levulinic acid. In that the molecular formula corresponds to  $C_{10}H_{16}O_6$ , Harries<sup>12</sup> concluded that the structure of rubber was that of polymerized 2,6-dimethyl-1,5-cyclo-octadiene. The reactions may be represented as follows:

Harries<sup>13</sup> later modified his views and wrote the structure of the rubber molecule as  $(C_5H_8)_x$  or  $C_{2x}H_{10}$ :

<sup>11</sup> C. D. Harries, *Ber.*, 1904, 37, 2708; *J.C.S.*, 1904, 86 (1), 757.

<sup>12</sup> C. D. Harries, *Ber.*, 1905, 38, 1195; *J.C.S.*, 1905, 88 (1), 364.

<sup>13</sup> C. D. Harries, *Ann.*, 1914, 406, 173; *Chem. Abs.*, 1915, 9, 283.

This structure is based on the fact that  $\alpha$ -isocaoutchouc<sup>14</sup> forms an ozonide which on decomposition yields

and the corresponding acids. The caoutchouc molecule is thus considered as built up of a 20-carbon ring containing 5 olefin linkages.

Pickles<sup>15</sup> considered rubber to be a long chain built up of isoprene units by 1,4 conjugation, with the ends joined to form a closed ring:

The number of isoprene units was uncertain but it was postulated to be in the neighborhood of eight.

A series of investigations on the structure of natural rubber were carried out by Midgley and Henne.<sup>16</sup> The destructive distillation of crepe rubber yielded largely isoprene, dipentene and heveen ( $\text{C}_{16}\text{H}_{24}$ ) together with other hydrocarbons in smaller quantity. The compounds which were identified consisted of molecules which could easily have been derived from the rubber unit

by the processes of hydrogenation, dehydrogenation, double-bond migration or auto-addition. In the case of sodium rubber (prepared by boiling isoprene with liquid sodium-potassium alloy) pyrolysis gave a decreased yield of the unsaturated compounds, isoprene and dipentene, an increased amount of pentenes and a small amount of saturated hydrocarbons.<sup>17</sup> The last were entirely absent in the natural-rubber distillate. The destructive distillation of ebonite yielded 2-methylthiophene, 2,3-dimethylthiophene, 2,4-dimethylthiophene, 2,5-methylethylthiophene and m-xylene.<sup>18</sup>

When rubber itself is heated in a vacuum the macromolecules decompose into residues of 20-50 isoprene units, which in turn form polycyclorubber, and into smaller residues which form isoprene, dipentene and sesquiterpenes.<sup>19</sup> A similar cyclorubber can be obtained by the destructive distillation of rubber in a stream of carbon dioxide under atmospheric pressure. Other products obtained consist of dipentene, isoprene and hexadiene. Dipentene occurs in the greatest quantity. These products are not only decomposition products of rubber but also of the polycyclorubber. The change of normal to cyclorubber can be represented thus:

<sup>14</sup>  $\alpha$ -Isocaoutchouc is the product obtained by removal of the halogen acid from the rubber hydracid by means of bases; it is not identical with ordinary caoutchouc. See Chapter 55.

<sup>15</sup> S. S. Pickles, *J.C.S.*, 1910, 97, 1088.

<sup>16</sup> T. Midgley, Jr., and A. L. Henne, *J.A.C.S.*, 1929, 51, 1215; 1931, 53, 203. T. Midgley, Jr., A. L. Henne and M. W. Renoll, *ibid.*, 1931, 53, 2733; 1932, 54, 3343, 3381.

<sup>17</sup> T. Midgley, Jr., A. L. Henne and A. F. Shepard, *J.A.C.S.*, 1932, 54, 381.

<sup>18</sup> T. Midgley, Jr., A. L. Henne and A. F. Shepard, *J.A.C.S.*, 1932, 54, 2953.

<sup>19</sup> H. Staudinger and W. Widmer, *Helv. Chim. Acta*, 1926, 9, 529; *Chem. Abs.*, 1926, 20, 3587. H. Staudinger and E. Geiger, *Helv. Chim. Acta*, 1926, 9, 549; *Chem. Abs.*, 1926, 20, 3588.

Staudinger and his co-workers<sup>20</sup> have brought forth a mass of evidence to show that rubber is built up of long chains of conjugated isoprene units with the formation of a linear polymeric structure.

The average weight of the rubber molecule is exceedingly large—perhaps as high as 70,000.

FIG. 140.— Latex Particle.

The commonest dispersion of rubber is the naturally occurring emulsion known as latex. The latter is secreted in small vessels and sacs located in the cortical tissue of plants belonging to the orders *Euphorbiaceae*, *Urticaceae*, *Apocynaceae* and *Asclepiadaceae*. The rubber is found in small globules suspended in a watery fluid which also holds certain proteins, carbohydrates and a small proportion of salts in

solution. If the latex is not to be worked up into rubber directly, ammonia is added to prevent putrefactive changes which otherwise take place and which result in coagulation. If an acid is added, the rubber separates in solid flakes or curds, this being a method commonly employed to obtain rubber. However, heat and astringent plant juices will produce the same effect.

In applying protective films to surfaces, the simplest method is to use a dispersion.<sup>21</sup> For example, a layer of rubber isomer<sup>22</sup> may be deposited on an object from solution followed by a layer of rubber from an aqueous dispersion.<sup>23</sup> The deposited material is then dried and vulcanized. A dispersion of rubber isomer in gasoline or benzene is stated by Geer<sup>24</sup> to produce a film which is resistant to those vapors and gases which corrode metals.<sup>25</sup> Hard-rubber varnishes can be made by dissolving rubber in a volatile solvent and vulcanizing at 125°C.<sup>26</sup> The product is rendered colloidal by heating under pressure at 180°C. Hardened rosin or cumarone resin can be added to increase the ease of application.<sup>27</sup> Shepard and Schmitt<sup>28</sup> have described a quick-drying composition prepared by heating a mixture of devulcanized rubber, rosin and tung oil until homogeneous. Benzene is added to the resultant material as a diluent.

It was pointed out by Smith, Garnett and Dean<sup>29</sup> that an insulating compound may be made by mixing wholly or partially deresinated gutta-percha or balata with petroleum jelly as a softener. Natural or synthetic rubber may also be added. In mixtures containing 15 per cent of petroleum jelly, tendency to sweat is overcome by heating to about 50°C.<sup>30</sup> Purified rubber in conjunction with 1-20 per cent of "Superla wax" (m.p., 71-77°C.), ozokerite or ceresin has been utilized by Kemp and Ingmanson<sup>31</sup> for a similar purpose. The same workers developed a process in which resin is extracted from gutta-percha, separated into alban and fluavil and the former restored to the gutta-percha. High-frequency submarine cables can be insulated with the body formed. Alban from other materials (chicle) may also be added to deresinated gutta-percha and then incorporated in rubber.<sup>32</sup> Cold alcohol is used as a selective solvent for fluavil to accomplish the separation from alban. The addition of as much as 15 volumes of asphalt to 100 volumes of rubber has been reported as improving the physical properties of the latter.<sup>33</sup>

<sup>22</sup> The term "rubber isomer" is applied to the hydrocarbons formed from rubber by the various agencies mentioned later in this chapter. They are less unsaturated than rubber, due probably to the mutual saturation of some of the double bonds to form cyclic structures.

<sup>23</sup> Artificial aqueous dispersions of rubber have been prepared by W. B. Pratt, *British P.* 217,612, 1922; *J.S.C.I.*, 1924, 43, 757B. See also J. B. Tuttle, *India Rubber World*, 1923, 67, 213, 291.

Goodenow<sup>34</sup> sprayed finely divided kauri or Manila copal on a thin sheet of uncoagulated latex which was then milled. The product was dissolved in turpentine, naphtha or carbon tetrachloride, evaporated to any desired extent and used as an adhesive. This cement was said to have the elasticity of rubber but much better weathering properties. In a related procedure, a solution of an alkali sulphate, silicate or carbonate is mixed with latex and then a soluble aluminum, calcium, barium or zinc salt is added to coagulate the rubber and precipitate an insoluble salt as a filler.<sup>35</sup>

#### PRODUCTS OF THE ACTION OF HEAT ON RUBBER

Mention has already been made concerning the work of Midgley, Henne and Shepard. By distilling balata and gutta-percha, it is possible to obtain products resembling linseed oil and turpentine.<sup>36</sup> Davies<sup>37</sup> found that the simple action of heat on rubber, without distillation, in the presence of magnesium or a magnesium alloy furnished a liquid miscible with oils. Further heating produced a putty-like mass; prolonged heating yielded a resin. The distillate from unvulcanized rubber, employing the same catalyst and heated in an autoclave at 240-300°C., gave rise to material which was suggested for use in paints and varnishes.<sup>38</sup> Vulcanized soft rubber or crude rubber depolymerized by melting, when mixed with molten bitumen and fibrous fillers (asbestos), has been suggested for coating pipe-lines and cables. Layers of fabric paper or pasteboard may be superimposed.<sup>39</sup>

Adhesives and insulating coatings have been obtained by Breuers<sup>40</sup> through heating rubber at 150-300°C. The rubber was first mixed with an equal weight of cyclohexane. A porous adsorbent carbon, slightly acidulated, or bleaching earth was also added in amounts of 10-50 per cent based on the weight of rubber. The product was a transparent resinous body, softening at about 50°C. and forming a thin liquid at 120-150°C. On hydrogenation it formed a solid and almost colorless resin. Butler<sup>41</sup> liquefied crude rubber by dissolving it in benzene, adding carbon tetrachloride to render the solution noninflammable and heating for 2-3 hours at 100°C. The product was utilized either alone or with added resins, oils, thinners or pyroxylin as a surfacing composition. The plastic, adhesive mass made by heating rubber at 200-350°C. followed by treatment with an inorganic acid is said to be of value in impregnating bandages.<sup>42</sup> Schidrowitz<sup>43</sup> reported that the material formed by vulcanizing latex containing ammonia (to prevent coagulation), sulphur and zinc oxide is superior in aging-properties to rubber which has been vulcanized in the dry state.

## PRODUCTS FROM THE OXIDATION OF RUBBER

The physical and chemical changes which take place in rubber on exposure to atmospheric oxidation have been frequently investigated. As early as 1861, Hofmann<sup>44</sup> observed that gutta-percha absorbed oxygen from the atmosphere, changing to a hard, brittle material. When thin films of acetone-extracted crepe rubber and balata hydrocarbons are exposed to oxygen at 85°C., rubber absorbs approximately 4 atoms of oxygen per unit of  $C_{10}H_{16}$ , whereas balata absorbs about 5 atoms.<sup>45</sup> Carbon dioxide, water, formic acid and formaldehyde can be identified in the volatile oxidation products of rubber at room temperature<sup>46</sup> whereas the solids consist of amorphous acidic substances, free from aldehyde and ketone groups but containing a small amount of peroxides.<sup>47</sup> By carrying out the oxidation with potassium permanganate in neutral or alkaline solution a series of complex, pale yellow or colorless, oxygenated, resinous products can be obtained.<sup>48</sup> These substances melt below 100-160°C. and are insoluble in acetone, alcohol or alkalies, but readily soluble in ether, benzene and ethyl acetate. Formic, acetic, oxalic and levulinic acids were also isolated. Treatment of rubber in carbon tetrachloride with chromyl chloride and decomposition of the primary product with water furnished a brown aldehydic resin. Mastication of rubber appears to entail an oxidation process.<sup>49</sup> Peroxides can be detected in the masticated product, and the oxidation reaction probably shortens the long rubber molecules.

Rubber, either in the solid state, in solution or in the form of a dispersion, when treated with an aliphatic per- acid (peracetic) or with an oxidizing mixture (acetic anhydride mixed with hydrogen peroxide) forms powdery, fibrous solids, which are more soluble in organic solvents than the original rubber and which can be added to varnishes and lacquers.<sup>50</sup> The oxidation is carried out at a temperature above 45°C. Since these materials become plastic when heated, they have been suggested as substitutes for shellac and celluloid. The polyhydroxy compounds formed by hydrolysis<sup>51</sup> may be hardened by condensation with an aldehyde. Below 80°C., acetyl peroxide and benzoyl peroxide form similar products. Rubber, for example, dissolved in chloroform, is treated with a peracetic acid mixture obtained by adding hydrogen peroxide and sulphuric acid to acetic anhydride. In this way Hopff, Ebel and Valko<sup>52</sup> produced a light yellow, tough, elastic material.

Cf. the oxidation of a rubber solution with air or ozone in the presence of cobalt inoleate, H. P. Stevens and W. Young, *British P.* 417,912, 1933, to Rubber Growers' Assoc., Inc.; *Brit. Chem. Abs. B*, 1934, 1112. Oxidized rubber made in this manner (Rubbone "B,"  $C_{10}H_{16}O$ ) has been suggested as a binding material for moldings, as an ingredient for electrical insulating varnishes, paints, lacquers and adhesives. Rubbone is classified as a "drying resin" and the surface in contact with air during stoving oxidizes and "case-hardens." It may also be vulcanized with sulphur or sulphur monochloride. (See also, *Synthetic and Applied Finishes*, 1935, 6, 8; *J. S. C. I.*, 1935, 54, 221.)

<sup>51</sup> The original product is a partially acetylated hydroxy acid which, if monobasic, possesses a molecular weight of at least 1000. G. F. Bloomfield and E. H. Farmer, *J. S. C. I.*, 1934, 53, 121T. See also J. A. Mair and J. Todd, *J. C. S.*, 1932, 386. B. Kagan and N. Sukhareva, *J. Rubber Ind. (U. S. S. R.)*, 1934, 11, 46; *Chem. Abs.*, 1935, 29, 954.

<sup>52</sup> H. Hopff, F. Ebel and E. Valko, *U. S. P.* 1,983,448, Jan. 22, 1935, to I. G. Farbenind. A.-G.;

Prolonged heating of latex (containing no ammonia) with hydrogen peroxide followed by preservation with ammonia is said to furnish a good adhesive.<sup>55</sup> According to Watkins,<sup>54</sup> rubber deposited from an aqueous dispersion can be made non-tacky by treatment with a solution of an oxidizing agent, e.g., a halogen, dichromate, hypochlorite, permanganate or chromic acid. The action of benzoyl peroxide in vulcanizing rubber has been studied by Van Rossem and co-workers.<sup>55</sup> The conclusion was reached that loss of solubility in vulcanized rubber is caused by the formation of bridges through polymerization and dehydrogenation of the rubber molecules.

The sizing of paper with latex to increase its elasticity<sup>56</sup> has been found to have no special advantage since in the course of several months the latex undergoes gradual oxidation.<sup>57</sup> The addition of 5 per cent of carbon black is reported to have a beneficial effect in protecting crude rubber against the action of sunlight.<sup>58</sup>

### NITRATION OF RUBBER

The treatment of purified rubber in carbon tetrachloride solution at 0°C. with nitrogen peroxide, followed by the action of oxygen, leads both to oxidation of the rubber and to combination of a certain amount of nitrogen. However, no simple derivative has been isolated. Nitric acid yields a heterogeneous product containing an oximino group.<sup>59</sup> By the use of dilute nitric acid, Gorgas<sup>60</sup> converted rubber into two substances; one, nitrogenous and soluble in acetone; the other, non-nitrogenous and insoluble in this solvent. When urea was added to the nitric acid previous to nitration, a yellow, friable mass, free from nitrogen, was obtained. Fisher<sup>61</sup> found that rubber (500 g.) dissolved in carbon tetrachloride (6.25 l.), when agitated with 500 cc. of concentrated nitric acid for an hour, gave 833 g. of a material having the approximate formula  $(C_5H_7NO_2)_x$ . This substance was soluble in acetone and nitrobenzene, but insoluble in benzene. Its use for impregnating, coating and insulating materials was suggested. The product separated from the reaction mixture in yellow flocks and was purified by filtering and washing free from acid. It decomposed above 136°C., but, when treated with methyl sulphate, a substance stable up to 300°C. was formed. Vulcanized rubber, when submitted to the same process, yielded closely similar products.

Fischer<sup>62</sup> prepared a somewhat different substance by dissolving rubber in concentrated nitric acid. The product flocculated out on dilution with water. It was soluble in benzene and, when its solution was evaporated, remained as a film of brownish yellow varnish. With more dilute nitric acid, e.g., 1-3 parts of 50

per cent acid to 100 of rubber in 400-600 parts of solvent, Oeckinghaus<sup>55</sup> has been able to produce rubber solutions characterized by having a low viscosity. Their use in spreading and dipping processes was proposed. The stickiness and slow-drying properties of a related coating (from the action of 1 part of 53 per cent nitric acid on 10 parts of rubber in 90 parts of benzene) were diminished by adding 0.5 part of antimony trichloride or phthalic acid.<sup>56</sup>

By milling rubber at 80°C. with about one-third its weight of p-nitrosodimethylaniline a sticky reaction product is obtained.<sup>55</sup> It is stated that this material, when allowed to mature for 24 hours after mastication, is useful for bonding rubber with metals or wood. It is soluble in benzene and may be employed in varnishes and lacquers. The reaction of nitrosobenzene on rubber has been studied by Bruni and Geiger.<sup>56</sup> A benzene solution of rubber and nitrosobenzene was heated on a water bath for 15 minutes, then cooled and poured into petroleum ether, yielding a yellow flocculent precipitate decomposing at 135-140°C. It analyzed for  $C_{11}H_{11}ON$  and was probably

#### HYDROGENATION OF RUBBER

Rubber is essentially an unsaturated hydrocarbon, although early investigators stated that it could not contain normal olefinic linkages since it was not very readily hydrogenated. However, evidence for the presence of double bonds in rubber was shown by Pummerer and Burkard<sup>57</sup> who succeeded in reducing a dilute solution of highly purified rubber in hexane and in methylcyclohexane by means of platinum black activated with oxygen.<sup>58</sup> This hydorrubber was similar to rubber itself in that it was highly elastic; it differed in that it was colorless, colloiddally soluble in ether and susceptible to oxidation especially when catalysts were employed.

At about the same time, Staudinger and Fritsch<sup>59</sup> succeeded in completely hydrogenating rubber by employing high temperatures and pressures (270°C. and 100 atmospheres). The hydorrubber was a colorless transparent mass without the elastic properties of ordinary rubber. Its solutions did not decolorize bromine; in sunlight a substitution product was formed.

In a similar reduction for the preparation of hydorrubber the metals of the sixth group of the periodic table are utilized as catalysts.<sup>70</sup> Lower temperatures can also be used for the hydrogenation;<sup>71</sup> for example, a 0.9 per cent solu-

tion of rubber (mol.wt., 45,000 by viscosity measurements)<sup>72</sup> in methyleyclohexane was reduced, employing a platinum catalyst and carefully excluding air. With nickel as a catalyst, a temperature as low as 100°C. could be used. The molecular weight of the product was 31,000 indicating relatively little cracking. The hydro-rubber by this procedure is swelled by solvents to give highly viscous solutions and in the solid state is elastic. Its saturated character is revealed by resistance to oxidation in air and by its stability in both the solid and the liquid states.<sup>73</sup> It is largely on the characteristics of this hydorrubber that Staudinger based his belief that the physical properties of rubber are due to the long molecular chain and not to the double bonds present.<sup>74</sup> Harries and Evers<sup>75</sup> have also prepared what may be a form of hydorrubber by removing chlorine from rubber hydrochloride with zinc dust. This compound has a general semblance of gutta-percha; it is unsaturated and analysis indicates the formula,  $(C_{10}H_{18})_x$ .

By catalytic reduction Geiger<sup>76</sup> prepared hydrobutadiene rubber as an easily soluble, syrupy liquid. Further, he found that hydrogenated balata and gutta-percha are very similar to ordinary hydorrubber. In the preparation of hydro-gutta-percha equal weights of nickel and gutta-percha were treated with hydrogen at 260-300°C. The product was soluble in hydrocarbons, chloroform and carbon tetrachloride, but insoluble in acetone and alcohol. Hydrogenated methylrubber also closely resembles hydorrubber.<sup>77</sup>

Pyrolysis of Staudinger's hydorrubber at 350-400°C. yielded hydrocarbons with only one double bond. The smallest molecule was a pentene, 2-methyl-1-butene, whereas from the higher fractions were isolated hydrocarbons,  $C_{15}H_{30}$  and  $C_{50}H_{100}$ . The presence of the latter substance shows that hydorrubber must have an exceedingly high molecular weight.<sup>78</sup> In just the same way as the hydrocarbon of rubber itself is not considered as a single chemical substance, hydorrubber is thought by Staudinger to embrace a series of polymer homologues of varying complexity, depending on the procedure used in the hydrogenation.

#### USES OF HYDORRUBBER

Compared to the other types of rubber derivatives, hydorrubber has been used for relatively few commercial purposes. The material obtained by raising the temperature slowly from 100° to 280°C. during hydrogenation at 80-150 atmospheres is stated to be sufficiently strong to be employed in uniting the sheets of safety glass.<sup>79</sup> Hydorrubber has been used both alone<sup>80</sup> and with gutta-percha, balata and natural rubber<sup>81</sup> as insulation for submarine cables. Albumin was removed from the constituents of the insulation by heating with alkali and washing.<sup>82</sup>

Plauson<sup>81</sup> proposed that the oils produced by the catalytic reduction of rubber at 130-200°C. be used in the preparation of paints and varnishes and as impregnating media for paper, cloth and leather. Hydrogenation of rubber at 270°C. while dissolved in a medium petroleum distillate furnishes a material which is stated to improve lubricating oils. Thus, 4 per cent added to a certain oil raised the viscosity from 1.95°E. at 100°C. to 2.3°E. and the viscosity index from 74 to 93.<sup>84</sup>

#### PRODUCTS FROM RUBBER AND SULPHURIC ACID OR SULPHONIC ACIDS

The transformation which takes place on treating rubber with sulphuric acid has been investigated by Kirchhof.<sup>85</sup> With carbon tetrachloride as a solvent a yellowish-white, brittle, amorphous powder was formed. It was concluded that this substance was a new hydrocarbon chemically and physically distinct from rubber. It had lost its typical rubber properties, including part of its unsaturation. The formation of an amorphous compound with formaldehyde was also observed. Fisher<sup>86</sup> has developed a number of derivatives of this type.

Cellular products were obtained by heating rubber (containing sulphur) with compounds of the general formula  $R-SO_2-X$ , e.g., a mixture of p-toluenesulphonic acid and sulphuric acid.<sup>87</sup> Shellac-like bodies may be made by heating a mixture of rubber and 1/10 of its weight of an organic sulphonic acid for 3-4 hours at 130°C. After about 1 hour, the temperature within the mass rises to 200-400°C. and bubbles of gas are given off. The artificial shellac is soluble in benzene, p-cymene, turpentine, carbon tetrachloride, tetralin, decalin and molten camphor, but insoluble in alcohol, ether, acetone, glacial acetic acid, amyl acetate, water, dilute acids and alkalis. Precipitation from solution by alcohol yields a whitish powder, softening at 90-100°C. and melting at 110-130°C. Pigments and fillers may be incorporated and hot pressed to form molded articles said to have good dielectric properties.<sup>88</sup>

The treatment of rubber with small amounts of sulphuric acid also yields tough, highly heat-plastic materials.<sup>89</sup> Five parts by weight of concentrated sulphuric acid are diluted with 1.25 parts of water and mixed with 2 parts of an inert material (titanium dioxide) to form a paste. This is then milled into 100 parts of rubber and heated in sheets at 125-130°C. for 15-20 hours. It is also possible to treat the rubber with a mixture of sulphuric acid and a sulphonic acid or a sulphonyl chloride.<sup>90</sup> Another non-tacky, thermoplastic substance was obtained by treating rubber with p-toluenesulphonic acid and sulphur.<sup>91</sup> Depending

upon the proportion of reagents used and the temperature and duration of heating, resilient, elastic products, resembling soft vulcanized rubber, tough, thermoplastic, balata-like substances or a hard, friable, shellac-like material resulted.

The products formed by the action of organic sulphonic acids on rubber have been recommended for the insulation of marine cables.<sup>92</sup> The reaction is carried out in the following manner: 3 parts of pine tar and 7 of concentrated sulphuric acid are worked into 100 of crude rubber and the mixture heated in an oven until a marked rise in temperature is noted (200-250°C.). This requires about 75 minutes at 130°C., heating being then continued for 2 hours, until a maximum temperature is noted. After cooling, the product is masticated in a warm mill and washed free from impurities. In order to soften the mass, various materials are added, e.g., turpentine, phenol, naphthalene, paraffin, oleic acid, furfural, stearic acid and phthalic anhydride.<sup>93</sup> A similar moldable body, which may be used in the production of insulation, radio parts and phonograph records, is produced by the action of sulphonyl chlorides and sulphuric acid, either together or separately, upon a mixture of crude rubber, vulcanized rubber scrap and pine tar.<sup>94</sup> Another thermoplastic material has been prepared by Winkelmann<sup>95</sup> through the use of a multivalent metal and an organic sulphonic acid.

The plasticity of the products from rubber and substituted sulphonic acids has also been modified by incorporating a wax or an oil of a low water-absorption capacity.<sup>96</sup> Thus, a composition for making sound records is prepared by mixing 300 parts of the hard material (produced from rubber, sulphuric acid and p-toluenesulphonic acid) with 100-250 parts of infusorial earth, 100-300 of ferric oxide, 10-50 of gas black, 10-50 of cotton flock and 10-50 of paraffin, stearic acid or palm oil.<sup>97</sup>

Incorporation of 10 per cent or more of diethyl sulphate with rubber, followed by heating for 8 hours at 125-140°C., yields a tough, stable, thermoplastic material dark in color.<sup>98</sup> It dissolves in the well-known rubber solvents including benzene, carbon tetrachloride and carbon disulphide, but is insoluble in alcohol, ether, water and dilute acids or alkalis.

A rubberized paint is obtained upon dissolving the product formed by heating rubber with phenolsulphonic acid for 6 hours at 140°C. Pigments, fillers, flowing-agents and preservatives or antioxidants are added.<sup>99</sup> Gray<sup>100</sup> reports that tests on this paint indicate resistance to chemical action and to penetration by water and that it is satisfactorily adhesive and elastic. The rubber isomer can also be employed in a nitrocellulose lacquer providing the solvent in the latter contains

toluene.<sup>101</sup> A further application of such transformation products is as undercoatings for cellulose esters.<sup>102</sup>

A laminated stock for battery cases has been formed by superimposing sheets of thermoplastic material and heat-curable natural rubber followed by vulcanizing together.<sup>103</sup> A typical formula for the synthetic layer consists of heat plastic from rubber and p-phenolsulphonic acid (86 parts), aldol- $\alpha$ -naphthylamine (3 parts), benzidine (1 part) and tung oil (10 parts).

Fisher<sup>104</sup> applied the name "Thermoprene" to the products made by heating raw rubber with the above-mentioned sulphonic compounds. These materials differ from vulcanized rubber in having the same empirical composition,  $(C_5H_8)_x$ , as the original rubber, i.e., they contain no combined sulphur. Their properties

Courtesy Parrel-Birmingham Co., Inc.

FIG. 141.—Laboratory Mill for Rubber and Other Plastics.

vary with the agent used and the time and temperature of heating, but in general resemble either gutta-percha, balata or shellac.<sup>105</sup> All three types combine with sulphur to form hard products which are no longer thermoplastic and are insoluble in organic solvents. The purified chief component of the shellac-like material could not be hydrogenated catalytically but was nitrated, forming a compound,  $C_6H_7NO_2$ .

A related thermoplastic conversion-product of rubber is described by Robinson.<sup>106</sup> Rubber is liquefied by mastication and by heating in an atmosphere of carbon dioxide at 250-270°C. The liquid is then subjected to treatment with sulphuric acid or a sulphonic acid at 150°C., yielding a rather hard black mass

(softening point 100°C.). By mixing together equal parts of this material and crepe rubber an adhesive for uniting rubber to fabrics has been obtained.<sup>107</sup> Another adhesive, suggested for uniting rubber to metal,<sup>108</sup> is produced by creaming latex with a weak organic acid, adding a strong acid such as sulphuric acid, evaporating the volatile material and baking at 150°C. Geer<sup>109</sup> has also employed the balata- or shellac-like isomers as adhesives, using benzene as a solvent and tung oil or castor oil as softeners. A very similar material has been produced through the action of the acid on rubber mixed with balata and gutta-percha resins.<sup>110</sup> For uniting rubber to metals, glass or hard rubber, an adhesive obtained by the action of formaldehyde on rubber in the presence of hydrochloric, phosphoric or sulphuric acid has been proposed.<sup>111</sup>

Rubber and the polymerization products of butadiene hydrocarbons have been dissolved in indifferent solvents and treated with carboxylic anhydrides, e.g., acetic anhydride, in presence of such acids as acetylsulphuric acid or sulphobenzoic acid. This transformed the rubber into a material intended for waterproofing and impregnating textiles.<sup>112</sup> Rubber or polymerized butadiene may also be sulphonated with chlorosulphonic acid in an organic diluent, e.g., ether, and used either in solution or emulsion form as tanning agents or as sizing- and dressing-assistants in the textile industry.<sup>113</sup> Oenslager's method of increasing the durability of rubber may be mentioned here.<sup>114</sup> Rubber which has been applied to articles of various shapes is treated with sulphur dioxide and oxygen under pressure.

#### ACTION OF NON-METALLIC HALIDES ON RUBBER

A further group of materials is obtainable by the action of metallic and non-metallic halides on rubber. Thus, aluminum chloride in conjunction with phthalyl chloride reacts with benzene solutions of the hydrocarbon below 100°C. to yield bodies which are said to have good wearing qualities after vulcanization.<sup>115</sup> Kirchhof<sup>116</sup> has studied the analogous action of benzoyl chloride on rubber in carbon tetrachloride solution using aluminum chloride as catalyst. This procedure yields a gray-white, spongy mass, which, after evaporation and extraction, remains as a brittle, amorphous body. The actual nature of the product varies greatly with the conditions of preparation. These benzylidene rubbers are pulverized with great ease and are thermoplastic above 100°C.

Rubber, in the presence of a solvent if desired, may also be treated with a phosphoryl halide at 15-40°C. The diluent is distilled off, and excess of the phosphorus compound is washed out with dilute ammonia leaving a material which softens at 100-110°C.<sup>117</sup> Plastic masses have been obtained also by treating rubber with a mixture of phosphorus trichloride and oxychloride<sup>118</sup> and with phosphorus compounds containing more oxygen than the oxyhalides.<sup>119</sup>

The halides of sulphur likewise have been used in rubber fabrication.<sup>120</sup> Twiss and Jones<sup>121</sup> and also Taylor<sup>122</sup> employed such substances as thionyl chloride, sulphur chloride and phosphorus pentachloride and pentasulphide in the surface-treatment of rubber articles to make them harder and more oil-resistant. Films and threads may be made by treating the polymerization products of hydrocarbons of the butadiene series with sulphurizing agents (e.g., sulphur dichloride) until the high-elasticity characteristic of rubber disappears.<sup>123</sup> This process may be applied also to polymers made from natural rubber, the product in either case being improved by incorporation of paraffin hydrocarbons of high molecular weight, cycloparaffins or waxes.<sup>124</sup> Resin-like bodies are obtained by treating a solution of rubber with sulphur chloride, sulphur dichloride or sulphuryl chloride and after removal of the solvent working up the material by the application of heat and pressure.<sup>125</sup> Gouillardon<sup>126</sup> has employed a solution of sulphur chloride in carbon tetrachloride to fasten rubber surfaces together. Rubber derivatives intended to find application in the manufacture of dyestuffs and pharmaceuticals have been obtained by the action of aryl or alkyl sulphur halides on rubber in an indifferent solvent. For example, a solution of p-nitrophenyl-sulphur chloride in carbon tetrachloride gives with rubber dissolved in the same solvent a bright yellow, additive product sintering at about 135°C.<sup>127</sup>

#### ACTION OF METALLIC SALTS ON RUBBER

Bruson<sup>128</sup> treated solutions of rubber with various metallic halides. Colored addition products were formed first, that from stannic chloride having the formula,  $(C_2H_5)_{10}SnCl_4$ . Removal of the metal halide with alcohol in an inert atmosphere yielded a benzene-soluble material which, when heated, became brittle and resembled shellac in appearance. Admission of air during the treatment with alcohol resulted in powdery insoluble oxides of the rubber polymers. In exhibiting this series of reactions, rubber resembles other unsaturated hydrocarbons, e.g., isoprene, cyclopentadiene and indene. To render surfaces of rubber articles hard and polishable, Geer<sup>129</sup> treated them with solutions of stannic chloride in ethylene dichloride

or ethyl acetate. A similar procedure has been employed to stabilize the color of rubber objects.<sup>120</sup>

When 10 per cent by weight of chlorostannic acid,  $\text{H}_2\text{SnCl}_6 \cdot 2\text{H}_2\text{O}$ , was milled into rubber and heated for 2-5 hours at 130-150°C., a tough, balata-like material resulted.<sup>121</sup> Long heating or excessive temperature formed a hard, ebony-like substance.<sup>122</sup> Both products are light colored and are soluble in benzene and petroleum hydrocarbons, but treatment with chlorine water increases their resistance to these solvents.<sup>123</sup> These bodies were proposed as plastics<sup>124</sup> and as binders for laminated material. A related composition was made by treating a benzene solution of rubber with chlorostannic acid at 65-80°C. After the viscosity had reached the desired value, the reagent was decomposed with water and the solvent distilled off.<sup>125</sup> An examination of the higher fatty acid salts of copper, manganese, iron and mercury, which disperse well with rubber, showed that all of these compounds are deleterious to the aging of vulcanized rubber.<sup>126</sup> On the other hand, Stine and Booge<sup>127</sup> have recommended the use of a rubber solution containing cobalt linoleate as a coating composition. After evaporation of the solvent, the cobalt salt brought about oxidation to a hard, durable, waterproof film.<sup>128</sup> A further reaction of metallic compounds is the reversible vulcanization by Grignard reagents and zinc alkyls observed by Midgley, Henne and Shepard.<sup>129</sup>

The halides of the amphoteric metals are reported as especially adapted to the preparation of thermoplastic materials.<sup>130</sup> Some of the halides of aluminum, chromium, iron, antimony, bismuth, manganese, tin, zinc, vanadium and zirconium are reported to be satisfactory for this purpose. The production of a thermoplastic body using ferric chloride, for example, is carried out as follows: 10 parts by weight of ferric chloride are milled into 100 parts of crude rubber, and the mass is subjected to dry heat at 160°C. for 15 hours. A strongly exothermic reaction takes place between the salt and the rubber, the temperature rising to 200-250°C. The product is a hard, brittle, heat-plastic material with a relatively low softening point. It is black in color, breaks with a conchoidal fracture and chemically is more saturated than the rubber from which it was prepared. The products from zinc bromide and zinc chloride are brown and somewhat transparent; those from antimony chloride or bromide are yellow; and those from bismuth chloride, a light gray. There is a tendency for the activity of the halide to increase with increasing atomic weight of the halogen atom, which may explain the inactivity of the fluorides in bringing about this type of reaction.

Gray<sup>141</sup> reports that turpentine when heated with stannous sulphate yields a material useful for bonding metal to rubber. The same investigator also used a mixture of a heat-plastic rubber isomer with a lead salt of a higher fatty acid, e.g., lead oleate, as a rubber cement.<sup>142</sup> Sebrell<sup>143</sup> developed a related method for securing fibrous or porous materials to metals or to each other. For example, 1346 g. of a cement containing 20.8 per cent of rubber were mixed with 30 cc. of a solution consisting of equal parts of benzene and thin pine oil. To this were added 4.9 cc. of anhydrous stannic chloride in 1200 cc. of benzene. The solution was heated at 80°C. for 2 hours and then cooled. The surfaces to be joined are coated with the liquid and pressed together at 80-100°C. for 10-30 minutes. A solution of sulphur and zinc butyl xanthate also has been proposed for joining rubber surfaces.<sup>144</sup>

#### PHENOLIC SUBSTANCES AND RUBBER

Plastic materials for electrical insulation may be obtained from rubber and formaldehyde, or rubber, formaldehyde and phenol. Such bodies have certain properties of both hard rubber and phenol resin. McGavack<sup>145</sup> stated that some chemical combination occurred between the rubber, phenol and aldehyde, i.e., the result was not merely a mixture of phenol resin and rubber. The following example illustrates the procedure: 15 kg. of pale crepe rubber are dissolved in 300 kg. of carbon tetrachloride, 25 kg. of sulphuric acid (sp.gr. 1.84) being stirred in to serve as a condensing agent. Forty kg. of 40 per cent formaldehyde solution are added, and the mixture is refluxed for 2-3 hours at 100°C. The resulting grayish-white product, containing free acid, formaldehyde and carbon tetrachloride, is treated with 100 kg. of water, and the carbon tetrachloride is distilled off, 90 per cent being recovered. The mass is washed with running water until free from acid, dried and milled on a cold mill. Then it is heated at 95°C. until dry. The brownish black powder, which is obtained finally, can be molded at 140-160°C. under a pressure of 3000-4000 pounds per square inch. It has a specific gravity of 1.05 at 18°C., softens at 130°C., has a transverse tensile strength of about 400 pounds per square inch and is almost insoluble in all acids, bases and organic solvents. The molded articles will take a high polish and may be machined, turned, sawed or drilled. If, in the above procedure, the formaldehyde is replaced by 15 kg. of butyraldehyde or 15 kg. of furfural, the products have similar properties but somewhat lower softening points.

A further variation is the use of latex, 100 kg. being treated with 650 kg. of carbon tetrachloride and the mixture shaken until a smooth emulsion results. Then, 30 kg. of phenol and 80 kg. of 40 per cent formaldehyde are added. After mixing, 40 kg. of concentrated sulphuric acid are run in and the mixture refluxed for 2 or 3 hours at 100°C., washed, dried and molded. Vulcanized rubber may also be utilized as a raw material<sup>146</sup> in which case it is first chlorinated. For example, 100 g. of ground vulcanized rubber, containing 1-5 per cent of combined sulphur, are dispersed or swollen in a container with 1 kg. of benzol. Chlorine is then introduced at the rate of about 10 cc. per minute per g. of rubber, until the rubber

<sup>141</sup> H. Gray, U. S. P. 1,697,275, Jan. 1, 1929, to B. F. Goodrich Co.; *Chem. Abs.*, 1929, 23, 1309.

<sup>142</sup> H. Gray, U. S. P. 1,782,036, Nov. 18, 1930, to B. F. Goodrich Co.; *Chem. Abs.*, 1931, 25, 437. See also H. Gray, U. S. P. 1,801,667, Apr. 21, 1931, to B. F. Goodrich Co.; *Brit. Chem. Abs. B*, 1931, 1148.

<sup>146</sup> J. McGavack, U. S. P. 1,640,364, Aug. 30, 1927, to Revere Rubber Co.; *Chem. Abs.*, 1927, 21, 3490. See also *Plastics*, 1927, 679.

molecule contains 56-58 per cent of chlorine. One hundred fifty g. of phenol and 150 g. of 40 per cent aqueous formaldehyde solution are added and the mixture boiled under reflux for 2-3 hours. The brownish emulsion is then steam distilled to remove excess of chlorine and solvent; and the solid product, containing 35 per cent of combined chlorine, is washed, dried and molded. Other phenolic substances, as well as higher aldehydes, may be used in the above process.<sup>147</sup>

Fisher<sup>148</sup> has suggested the production of a plastic material formed from rubber by the action of trichloroacetic acid. The following is an example of the general procedure: 100 parts by weight of a 5 per cent solution of rubber in benzene are mixed with 6 parts of trichloroacetic acid, and the mixture heated under reflux for 2 days. Then the solvent is distilled off and the solid residue is washed. The mass is homogenized by mastication or by redissolving in an organic solvent. In one modification of this method a phenol is employed. For example, 100 parts by weight of 5 per cent rubber solution, 10 parts of phenol and 6 parts of trichloroacetic acid are mixed and heated on a steam bath, the solid being recovered as before. These materials are tough and somewhat friable and are heat-plastic at ordinary molding temperatures. They are soluble in the common rubber solvents (e.g., benzene, gasoline and turpentine), but practically insoluble in alcohol, ether, acetone, aniline, water and dilute acids or alkalies. Rubber may also be made to yield thermoplastic materials by heating with a phenol and a third substance.<sup>149</sup> The latter may be one of a large number of compounds, including chlorinated rubber, rubber hydrochloride, aniline hydrochloride, trichloroaniline hydrochloride, mercuric chloride, stannic chloride, aluminum sulphate, naphthalene tetrachloride, m-nitraniline hydrochloride or pinene hydrochloride.

A further group of reagents suggested for converting rubber-phenol mixtures into moldable bodies includes sulphonyl chlorides and dilute sulphuric acid.<sup>150</sup> Vulcanized rubber when similarly heated at 100°C. with benzene, phenol and hydrochloric or hydrobromic acid yields an adhesive.<sup>151</sup>

#### MISCELLANEOUS PRODUCTS FROM RUBBER

Prolonged contact with thioglycolic acid converts rubber into a glassy resinous material of the formula,  $(C_6H_5-S-CH_2-CO_2H)_n$ .<sup>152</sup> Allowing polymerized butadiene to stand in dilute alkali is said to prevent resinification.<sup>153</sup> Cathode rays have been observed to transform rubber in a manner similar to vulcanization.<sup>154</sup> Rubber-impregnated fabrics (e.g., conveyor belts) have been rendered acid-resistant by alternate coatings of a thermoplastic rubber isomer and of an elastic mixture containing a natural gum-resin and a drying oil.<sup>155</sup>

<sup>147</sup> R. P. Courtney (British P. 356,769, 1930, to Bakelite Corp.; *Brit. Chem. Abs.* B, 1931, 1062) prepared a cement by incorporating rubber in an oil-modified phenol resin.

## Chapter 55

### Resins from Rubber II. Halogenated Rubber

The halogens react directly with rubber, gutta-percha or balata to form an interesting series of compounds possessing properties intermediate between those of rubber and the brittle natural resins. The extent of the halogenation in the case of chlorine can be varied to produce compounds containing as much as 70 per cent of halogen. This highly chlorinated rubber together with derivatives containing less chlorine furnish a graduated series of products with elastic properties varying from that of the original rubber to one of a tough, leather-like resin. The halogenated bodies are chemically inactive and are more soluble than the original stock in carbon tetrachloride, carbon bisulphide, chloroform, acetone and ether from which they may be precipitated by alcohol. The solutions possess much lower viscosity than those of the original material and find use as bases of coating compounds and lacquers. Although chlorine is ordinarily employed, both bromine and iodine react with rubber. The color of the halogenated compounds varies from a pale-yellow to pure white. They do not burn, and, when heated soften without melting; decomposition occurs before the true melting point is reached. They possess electrical insulating properties. When mixed with various fillers they form compositions which can be hot-molded; the final products are more tough than brittle, and can be worked into masses resembling leather. Moreover somewhat similar compounds are formed by the action of the hydrogen halides on rubber and related materials.

#### MECHANISM OF HALOGENATION

On the basis of the structure of the rubber molecule,<sup>1</sup> halogen could add directly to the unsaturated bond. Chlorine, for example, should furnish a chloro hydrocarbon containing 51 per cent of chlorine.

In practice, however, both addition and substitution occur inasmuch as hydrogen chloride is evolved. Moreover the compound, which is isolated, contains more halogen than the above equation would indicate.

Numerous explanations have been offered to account for this phenomenon. Kirchhof<sup>2</sup> suggested that the initial addition compound loses hydrogen halide and that the halogen then reacts on the newly formed unsaturated hydrocarbons. The reaction can be considered as taking place in the following stages:—

<sup>1</sup> See Chapter 54.

<sup>2</sup> F. Kirchhof, *Gummi-Ztg.*, 1932, 46, 497; *Chem. Abs.*, 1932, 26, 1827.

This last substance,  $(\text{C}_5\text{H}_4\text{Cl})_x$ , corresponds to a chlorine content of 68 per cent. The second phase of the reaction, as indicated, could take place with the formation of only one double bond, leading to a compound represented by the empirical formula  $(\text{C}_5\text{H}_4\text{Cl}_2)_x$ , and the presence of this material along with the final tetrahalogenated compound would account for the variation in the final products. As a matter of fact, derivatives containing approximately 70 per cent chlorine have been prepared.

McGavack<sup>a</sup> followed the chlorination reaction through its entire course by a method of gas analysis. The volume of chlorine passed into a solution of a known amount of rubber and the hydrogen chloride and unabsorbed chlorine coming off were measured by means of flowmeters. The results showed that substitution takes place almost exclusively during the early stages of the reaction but later diminishes in rate. Corresponding to the reduction in rate of substitution, the rate of addition increases accompanied by a gradual fall in temperature.<sup>a</sup> The final product has a chlorine content of approximately 65 per cent, which corresponds to that of a compound containing 3 substituted and 4 added chlorine atoms for each two  $\text{C}_5$  groups; thus  $(\text{C}_{10}\text{H}_{12}\text{Cl}_7)_x$  has 65.1 per cent chlorine content. In his experiments, McGavack also observed that the properties of the final product are influenced by the grade of rubber used, the type of apparatus, the intensity of light and the temperature of reaction. The course of the reaction and hence the chlorine content were found to be dependent, within limits, upon the type of solvent used and upon the temperature, substitution being favored by higher temperatures.

#### EARLY HISTORY OF HALOGENATION

Eck,<sup>b</sup> in a review of the early history of chlorinated rubber, called attention to the fact that the acid used by Fourcroy<sup>c</sup> (when the latter discovered that acids coagulate latex) was in fact chlorine water, the so-called oxidized muriatic acid.

<sup>a</sup> J. McGavack, *Ind. Eng. Chem.*, 1923, 15, 961.

<sup>b</sup> This is not inconsistent with the mechanism of Kirchhof, since the hydrogen chloride formed in that case also occurs in the initial stages of the reaction.

<sup>c</sup> L. Eck, *Gummi-Ztg.*, 1933, 47, 517; *Chem. Abs.*, 1933, 27, 2337.

<sup>d</sup> A. F. Fourcroy, *Ann. chim. phys.*, 1791, 11, 235. *Système des connaissances chimiques*, 1801, 8, 36.

For a long period rubber was thought to be resistant to chlorine; Berzelius,<sup>7</sup> for example, said that rubber tubes could be used in working with chlorine. Himly<sup>8</sup> reported the action of chlorine on the products of the destructive distillation of rubber and, in 1859, Traun<sup>9</sup> observed that chlorine, when passed into a solution of rubber in carbon disulphide, furnished a white substance which was no longer elastic or flexible.

FIG. 142.—Spongy Form of Chlororubber. This piece, eleven inches in diameter and about three inches thick, weighs 295 grams.

In the same year, Engelhard and Havemann<sup>10</sup> described the effect of gaseous chlorine on solid rubber and on gutta-percha. The action of the gas on the solid was slow and was accompanied by swelling, yielding a brittle, white mass which, after washing out the chlorine with water, was soluble in the usual rubber solvents. Reaction was accelerated by using a solution of rubber in chloroform or benzene, from which the reaction product could be precipitated by alcohol as a hard, white mass, which was soluble also in carbon disulphide. The addition of zinc or calcium oxides to the chlorinated solution was stated to facilitate the preparation of hard bodies.<sup>11</sup>

Helm<sup>12</sup> immersed small pieces or thin sheets of either rubber or gutta-percha

<sup>8</sup> Himly, *Dissertation Göttingen*, 1835.

<sup>9</sup> H. Traun, "Versuch einer Monographie des Kautschuks," Göttingen, 1859.

<sup>10</sup> G. A. Engelhard and R. F. H. Havemann, U. S. P. 25,175, Nov. 22, 1859. G. A. Engelhard and H. H. Day, *British P.* 2734, 1859.

<sup>11</sup> R. F. H. Havemann, U. S. P. 31,340 and 31,341, Jan. 29, 1861.

<sup>12</sup> J. Helm, Jr., U. S. P. 115,302, May 23, 1871.

in saturated chlorine water or in liquid chlorine and thus obtained a brittle mass which, after washing and drying, could be pressed in a hot mold. He found that a solution of rubber or gutta-percha in gasoline or benzene could be chlorinated by mixing with chlorine water or liquid chlorine (under pressure) and also suggested the addition of fillers (zinc oxide, Paris white, terra alba, ground glass or lime) before chlorination. The product was one of comparatively small chlorine content since the proportions used were about 3 parts of chlorine to 4 parts of rubber.

In subsequent studies made by Gladstone and Hibbert<sup>13</sup> chlorine was passed into a 1 per cent solution of rubber in chloroform exposed to diffused light. An immediate evolution of hydrogen chloride occurred and continued for a long period. Evaporation of the solvent yielded the chlorinated product in the form of yellowish scales. In every instance, both substitution and addition occurred and the best specimen contained 65.18 per cent of chlorine. Temperature had a definite effect on the course of the reaction.<sup>14</sup> Chlorination at 0°C. of a 1 per cent solution of rubber in benzene or chloroform yielded a product whose analysis (61.6 per cent of chlorine) approximated that which is represented by the formula,  $(C_{10}H_{14}Cl_2)_x$ .

#### CHLORINATION IN SOLUTION

Peachey<sup>15</sup> employed a method of chlorinating a 4 per cent solution of rubber in carbon tetrachloride. The mixture was agitated and cooled to absorb the heat generated during reaction, and chlorination was continued until the desired properties were obtained in the finished product. In this manner, chlororubber containing as much as 65 per cent chlorine could be prepared. Addition of camphor, either before or after chlorination, gave a material resembling leather. Peachey<sup>16</sup> also suggested the use of alkyl, alkylene and aryl halides as solvents and sulfuryl chloride or a mixture of bromine and chlorine as the halogenating agent. Corresponding reactions occur and similar products are formed when balata and gutta-percha are substituted for rubber. Even benzene and its homologues have been proposed as solvents,<sup>17</sup> the action of chlorine on the solvent being minimized by conducting the process in vessels made of stoneware or lead.

In another method, solutions of chlorine and rubber are mixed in the presence of water.<sup>18</sup> The latter absorbs the hydrogen chloride formed, thereby diminishing foaming and consequent loss of solvent. Further, if the water contains an oxidizing agent (sodium hypochlorite), the hydrogen chloride is oxidized returning chlorine to the reaction. The material finally obtained is an emulsion of water in chlorinated rubber solution.

The high viscosity of solutions of rubber in the customary solvents (which ordinarily limits concentrations to 3-5 per cent rubber) may be reduced by mastication of the rubber after it has been swollen in a solvent.<sup>19</sup> The viscosity of the chlorinated solution is particularly important when it is to be used as a varnish or lacquer since, as is well known, a paint of low viscosity is easier to apply. ber that has been depolymerized by mastication, irradiation with ultraviolet light<sup>20</sup> or by the action of copper oleate<sup>21</sup> yields chlorinated products which dissolve to form solutions of relatively low viscosity. Dyche-Teague<sup>22</sup> employed a method in which rubber is milled and then dissolved to the extent of 10 per cent in carbon tetrachloride or a similar solvent. The product of chlorination after distilling off the solvent contains 50-60 per cent chlorine. A 20-30 per cent solution of this material in benzene had a viscosity about equal to that of linseed oil.

Preliminary oxidation of rubber to give it approximately 1 per cent combined oxygen offers a means of reducing the viscosity of solutions of its chlorinated products.<sup>23</sup> Oxidation may be brought about by heating rubber in thin sheets at 60°C. in air or oxygen, or by exposure of thin sheets to ozone, followed by milling. The effect may be obtained also by passing air, oxygen or ozone into rubber solutions<sup>24</sup> and by the addition of benzoyl peroxide or sodium hypochlorite.<sup>25</sup>

As the solutions in which rubber is chlorinated are usually fairly dilute, the problem of obtaining the solid chlorinated rubber remains. Spencer<sup>26</sup> recovered the solid product by passing the solution of rubber under the surface of an agitated heated liquid (in which the solvent was immiscible), the latter being maintained at a temperature above the boiling point of the solvent. As the chlororubber rose to the surface in a porous, spongy or fibrous condition, the solvent passed off as a vapor. When water is employed as the heating liquid, its boiling point may be increased, if necessary, by the addition of glycerol.<sup>27</sup> Another procedure involved spraying chlororubber solution into steam which was maintained near or above the boiling point of the solvent.<sup>28</sup> Steam and solvent vapor were removed simultaneously.

#### CHLORINATION OF SOLID RUBBER

Action of gaseous chlorine on solid rubber is slow and normally penetrates to only a slight depth because of the protective action of the superficial layer of chlorinated material. To offset this, Ellis<sup>29</sup> advocated masticating rubber in an atmosphere of chlorine. If desired a small amount of solvent is added as a plasticizing agent. The product may be used in solution as a lacquer or varnish base or mixed with fillers to form a molding composition.

Edison<sup>30</sup> recommended chlorination of thin rubber sheets by chlorine gas containing the vapors of carbon tetrachloride, the latter acting as a softening agent.

<sup>30</sup> T. A. Edison, U. S. P. 1,495,580, May 27, 1924; *Chem. Abs.*, 1924, 18, 2266.

The resulting soft mass contains some hydrogen chloride, which is removed by washing. Chlorination of powdered, unvulcanized rubber without the aid of a solvent is described by Martin.<sup>31</sup>

The greater solubility of chlorinated rubber has been utilized to accelerate chlorination of solid rubber. By suspending thin strips or sheets of rubber in carbon tetrachloride,<sup>32</sup> the solvent dissolves off the protective coat of chlorinated product during chlorination and thus exposes fresh rubber surfaces to the gas. In this manner a more rapid reaction is secured. The final product is a 32 per cent solution of chlorinated rubber in carbon tetrachloride. The dry chlororubber contains 70 per cent of chlorine. It was found more satisfactory to add the rubber gradually to the solvent as the reaction proceeded and it was necessary to stir the mass vigorously to insure complete contact. Temperatures between 50°C. and the boiling point of the solvent were employed. Additions of small amounts of bromine or iodine to the solution accelerated chlorination. Another catalyst which has been suggested is a Japanese acid clay.<sup>33</sup>

#### EFFECT OF TEMPERATURE ON CHLORINATION

Ellis<sup>34</sup> found that the reaction between chlorine and rubber suspended in a solvent was accelerated and a higher degree of chlorination favored as the temperature approached the boiling point of the solvent. The operation is most conveniently carried out in a closed vessel provided with reflux and an agitator. Iodine in the proportion of 1 g. per kg. of solvent is an effective catalyst. The product is light yellow and is readily soluble in benzene or in ethyl acetate and yields a hard, tough, glossy film on the evaporation of the solvent.

Chlorinated compounds prepared near the boiling point of the solvent<sup>35</sup> do not subsequently split off hydrogen chloride, are relatively acid free, and serve directly as film-forming ingredients in lacquers.<sup>36</sup>

#### CHLORINATION UNDER PRESSURE

By conducting chlorination at high pressures without the use of a solvent, some of the expense incident to handling solvent and unavoidable losses in its recovery may be obviated. At the same time the increased pressure overcomes the sluggish reaction between the gas and the solid rubber.

Experiments in the author's laboratory<sup>37</sup> have shown that, using a lead-lined autoclave loosely packed with thin sheet rubber, reaction proceeds very slowly at pressures below 60 pounds per square inch, yielding a product having only 30 per cent chlorine. At pressures above 60 pounds per square inch chlorination is much faster and is more nearly complete. Due to swelling of the mass, the capacity of the autoclave is limited.

<sup>37</sup> Carleton Ellis and N. Boehmer, U. S. P. 1,544,534, June 30, 1925, to Chadeloid Chemical Co.; *Chem. Abs.*, 1925, 19, 2759.

A typical chlorination of this kind was carried out as follows: 100 grams of sheet rubber were loosely packed in a lead-lined autoclave and chlorine was introduced to bring the pressure to 80 lbs. per square inch. As the reaction proceeded, there was a slight rise in temperature, and the pressure gradually dropped in 16 hours to 50 lbs. per square inch. This pressure, caused largely by hydrogen chloride, was released and chlorine was re-introduced to 128 lbs. pressure. After each 24 hours this operation was repeated and at the end of 168 hours only an insignificant amount of hydrogen chloride was detected in the vented gas. Three hundred fifty seven g. of a white or light cream-colored mass containing 72 per cent of chlorine were isolated. Variations of the process were to omit venting hydrogen chloride if a low chlorine content was desired and to add chlorine continuously while venting at a rate slow enough to keep the pressure up to the desired point.

Liquid chlorine was found to be an effective chlorinating agent for solid rubber since it appears to be a good solvent for the reaction product.<sup>33</sup> Using an excess of chlorine at 70°C. and 323 lbs. pressure, chlorination was complete in 27 hours without any removal of hydrogen chloride. The product is a dark green viscous liquid from which, after reduction of the pressure, chlorine evaporates to yield a porous mass. On washing to remove hydrogen chloride and on drying this residue, a white or very light yellow material is obtained. It has been shown further that higher temperatures accelerate the reaction, but care must be exercised to prevent too much heating which discolors the product.<sup>33</sup> Another modification employs rubber which has been masticated with a small amount of solvent, furnishing (as has been noted above) a material which forms solutions of low viscosity.<sup>40</sup>

#### NEUTRALIZING AGENTS (ANTACIDS)

Inasmuch as chlorination is accompanied by the evolution of hydrogen chloride, it is necessary that acid be completely removed from the product before use. Even the greatest care in this respect does not prevent the generation of hydrogen chloride by the subsequent slow decomposition of highly chlorinated products. At elevated temperatures this decomposition may become rapid. To offset the tendency to split off hydrogen chloride, it has been found that the addition of basic compounds, e.g., aniline, toluidine and xylylene, diphenylamine, phenylene diamine and urea, are effective in stabilizing chlorinated rubber solutions.<sup>41</sup> On the other hand, the oxides of zinc, barium and magnesium may be used in pigmented paints and lacquers where solubility of the stabilizer in the mix is not essential.

A stabilized product is obtained by chlorinating rubber in carbon tetrachloride solution in the presence of sodium carbonate or potassium bicarbonate. When 55-65 per cent of chlorine has combined, the solution is heated to boiling for several hours.<sup>42</sup> Thus prepared, the material does not yield hydrogen chloride when heated up to about 180°C.<sup>42</sup> Another class of stabilizing agents includes the derivatives of ethylene oxide, (epichlorohydrin, phenoxypropene oxide, dimethylglycidol and phenylmethylglycidol).<sup>43</sup> Becker and Blömer<sup>44</sup> isolated chlororubber from solution in carbon tetrachloride by pouring the reaction mixture into alcoholic

potassium hydroxide. The product precipitated as a powder which was then stabilized by stirring at room temperature for 15-20 hours.

### RUBBER HYDROCHLORIDE

Rubber in solution reacts with hydrogen chloride to form substances simulating those formed by chlorine. The reaction may be expressed as follows:

Harries<sup>46</sup> prepared a compound corresponding to  $(\text{C}_{10}\text{H}_{16}\text{Cl}_2)_x$  by saturating solutions of rubber<sup>47</sup> in chloroform or benzene with hydrogen chloride and allowing them to stand 12 hours. The product, precipitated from solution by addition of alcohol, is white and elastic, becoming brittle on standing. It is soluble in benzene and chloroform but insoluble in ether and alcohol. It has no characteristic melting point; decomposition beginning at 145°C. becomes complete at 185°C. Treatment with pyridine or with sodium hydroxide solution removes hydrogen chloride from the compound, yielding a chlorine-free rubber. Weber<sup>48</sup> stated that moisture is necessary to the formation of a resinous hydrochloride and that without its presence sticky masses are formed. He further noted the partial decomposition of rubber hydrochloride when treated with organic bases and found that although hydrogen chloride splits off on heating, an amount of chlorine corresponding to about 18 per cent is held tenaciously even up to 100°C., indicating a stable compound of this composition.

Oenslager<sup>49</sup> proposed using a solvent for hydrogen chloride which did not dissolve rubber, e.g., ethyl acetate and similar esters.<sup>50</sup> Ethyl acetate exerts merely a softening action on rubber and dissolves as much as 20 per cent of dry hydrogen chloride. The procedure consists of immersing thin sheets of masticated rubber in a saturated solution of hydrogen chloride in ethyl acetate at room temperature for 36-48 hours. The product retains the shape of the original sheets and possesses a deep-amber, translucent, horny appearance. It is tough and hard and much more resistant than rubber to destructive agencies including oxidizing acids and the hydrocarbons, gasoline, kerosene and lubricating oil.<sup>51</sup>

Rubber will add hydrogen fluoride until a content of 30 per cent of fluorine is attained. Heat, however, decomposes this material and a plastic body containing about 2 per cent of fluorine results. The softening point of the product depends on the concentration of the acid employed. For example, the action of 69

and 85 per cent solutions on smoked sheets gives bodies softening at 90° and 155°C. respectively. Further, the more concentrated acid reacts faster, requiring only 6 hours as compared with 48 for the other.<sup>52</sup>

Ellis<sup>53</sup> devised a method for treating rubber with chlorine and hydrogen chloride in a series of reaction vessels. Each vessel is charged with the mixture of gases vented from the one above it. Chlorine is introduced into the first and, when the material in this is ready to be removed, a fresh vessel is inserted at the bottom of the series.

#### ACTION OF HYPOCHLOROUS ACID

Hypochlorous acid, like hydrogen chloride, adds to an unsaturated linkage and has found use in the halogenation of rubber. Inasmuch as hypochlorous acid is relatively un-ionized, it does not effect coagulation of the latex. The acid may be formed *in situ*, by passing chlorine directly into latex previously made alkaline with sodium carbonate. The first product formed according to Bloomfield and Farmer<sup>54</sup> was a light, fine, pale-yellow powder which approximated  $C_5H_7OCl$  in composition. Further treatment of latex with hypochlorous acid resulted in the replacement of hydrogen atoms by chlorine. When the chlorine content approached 45.8 per cent, the material was an insoluble, cream-colored powder. Not being coagulated by heat or acid, further chlorination was resorted to at 80-100°C. under acid conditions. With one sample of Malay latex the product was a white powder containing 51.1 per cent chlorine and was soluble in chloroform, cyclohexanone, cyclohexyl acetate and diacetone alcohol.

Agitation of rubber solutions with aqueous solutions of hypochlorous acid at 0-5°C. results not only in chlorination of the rubber but also addition of the acid, provided at least one molecular proportion of the latter is employed. The highest degree of chlorination was accomplished in chloroform solution by a 3-day treatment with 5 molecular proportions of hypochlorous acid. The product was a fine, white powder, soluble in chloroform, benzene and acetone, but insoluble in carbon tetrachloride. Analysis showed 66.0 per cent chlorine and 8.5 per cent hydroxyl. These proportions approximate the formula,  $(C_5H_7OCl_5)_x$ .

#### BROMINATION AND IODINATION

The action of bromine and iodine on rubber is somewhat analogous to that of chlorine and in most of the chlorination procedures either of these may be substituted. In general, the products formed are darker in color than the chlorine derivatives and it is difficult to introduce as large an atomic proportion of either bromine or iodine into the rubber molecule. It should be noted that the bromine and iodine compounds of rubber are much less soluble than the corresponding chlorine derivative. The catalytic effect of iodine on the chlorination of rubber has already been noted above. Rubber, gutta-percha and balata all add iodine monobromide and iodine monochloride. A solution of the latter was recommended by Kemp and Mueller<sup>55</sup> as a reagent for measuring the degree of unsaturation of rubber.

Bromine reacts directly on a chloroform solution of rubber. Hydrogen bromide is evolved and compounds of variable composition, approximating the formulas,  $(C_{10}H_{18}Br)_x$  and  $(C_{10}H_{15}Br)_x$ , are obtained.<sup>56</sup> Weber<sup>57</sup> prepared the tetrabromide of rubber and found it to resemble closely the corresponding chlorine compound. The rubber tetrabromide reacted readily with sodium ethylate presumably by the substitution of ethoxy groups for bromine.

A tetraphenoxy derivative of rubber was formed by adding rubber tetrabromide to molten phenol.<sup>58</sup> At 60°C., hydrogen bromide was evolved yielding a red-violet solution from which could be recovered an ochre-colored, pulverulent material, readily soluble in aqueous or alcoholic sodium hydroxide, alcohol, acetone, ether and ethyl acetate, but insoluble in benzene, chloroform, carbon disulphide and petroleum ether. Later this compound was shown to be 4,4'-dihydroxydiphenyldihydorrubber<sup>59</sup> since it can be methylated to form a dimethoxy derivative.<sup>60</sup> An analogous material produced at 90-95°C. appeared to be a tetraphenoxy-dihydroxy derivative. Compounds of this type split off phenol, however, when heated with sodium hydroxide solution.

The reaction of rubber with the halogens was at one time deemed to be practically the same as that of vulcanization with sulphur, but further study of the two series of derivatives has shown this view to be no longer tenable. Pearson,<sup>61</sup> for example, stated that rubber dipped in bromine was "vulcanized" immediately. A mixture of one part bromine and two parts iodine could be used for the same purpose, a hard compound being obtained when the treatment took place at 121°C. Likewise hypochlorite solutions were employed for the same purpose.<sup>62</sup>

Although Gladstone and Hibbert<sup>63</sup> reported no action between iodine and rubber in solution, Weber<sup>64</sup> obtained a compound corresponding to  $(C_{10}H_{18}I)_x$  by treating a rubber solution with iodine for 2 days. Iodine addition products could be obtained in chloroform solution by the catalytic action of sunlight.<sup>64</sup> A so-called "vulcanized" rubber results when a solution of 10 parts of rubber in carbon tetrachloride is treated with 1 part iodine dissolved in the same solvent.<sup>65</sup> A similar compound was prepared by Rasser.<sup>66</sup>

Hydrogen bromide forms addition compounds with rubber similar to those of hydrogen chloride, according to both Harries<sup>67</sup> and Hinrichsen, Quensell and Kindscher.<sup>68</sup> The latter obtained a compound corresponding to  $(C_{10}H_{18}Br)_x$ .

Although addition compounds of hydrogen iodide and rubber are much less stable, a di-iodo derivative corresponding to  $(C_{10}H_{18}I)_x$  has been prepared; this compound readily loses a molecule of hydrogen iodide.<sup>69</sup> Hinrichsen, Quensell and Kindscher<sup>70</sup> confirmed this observation concerning instability and were able to isolate with certainty only one compound corresponding to  $(C_{10}H_{17}I)_x$ .

Kirchhof<sup>71</sup> treated the sulphuric acid transformation products of rubber with bromine and obtained  $(C_{20}H_{30}Br_2)_x$ . These sulphuric acid transformation products are made by the action of concentrated sulphuric acid on solutions of raw rubber in carbon tetrachloride. Similar treatment of pale crêpe rubber yields a brittle red powder which is probably an oxidation product.

#### OTHER VARIETIES OF RUBBER

Thus far methods intended primarily for the preparation of halogen derivatives of rubber have been discussed. By rubber is meant the usual standard grade obtained from the tree, *Hevea brasiliensis*, and known as "pale crêpe" or "plantation para rubber." However, rubber latex, chicle, balata, gutta-percha and other grades and types of materials or artificial rubber may be used similarly. Reaction between halogens and such rubber-like materials are analogous to those of rubber itself. Chlorinated gutta-percha, for instance, resembles chlorinated rubber but possesses a somewhat yellow color.

The use of chlorinated balata or gutta-percha to provide a tough, flexible, nonflammable insulation for electrical conductors was advocated by Edison in 1890.<sup>72</sup> His procedure was to treat a solution of the material in a solvent unaffected by chlorine until a dried film of the treated substance was somewhat brittle and nonflammable. The desired degree of flexibility could be obtained by mixing the product with some of the raw material.

The addition compounds of gutta-percha with the hydrogen halides,<sup>73</sup> when treated with pyridine or sodium hydroxide solution, decompose into substances more closely resembling rubber than the parent substance. Gutta-percha dihydrochloride  $(C_{10}H_{12}Cl_2)_x$ , is tough when freshly made but becomes brittle on standing. Decomposition, with the evolution of hydrogen chloride, occurs at 170°C.; at 200°C. there is a complete breakdown.

#### VULCANIZED AND RECLAIMED RUBBER

Chlorination of vulcanized rubber is complicated by its insolubility in the usual solvents for raw rubber and also by the presence of sulphur or other vulcanizing agents. Bedford and Kelly<sup>74</sup> suggested a process consisting of, first, removing excess sulphur by extracting with acetone or with caustic alkali, suspending the material in carbon tetrachloride and then treating the suspension with gaseous chlorine. To increase the solubility of rubber after removal of the excess vulcanizing agent it is plasticized at 150-170°C. with a high-boiling solvent (pine oil, aniline, nitrobenzene and acetylene tetrachloride). The high-boiling solvent is removed by repeated dilution, and the rubber is precipitated with lower-boiling solvents and finally chlorinated in carbon tetrachloride, after first removing mineral fillers and pigments. The addition of sulphur (2 per cent) or sulphur chloride to a solution of raw rubber in carbon tetrachloride before chlorination is reported to yield a product similar to that from vulcanized rubber. Varnishes, lacquers and a thermoplastic molding material can be produced by chlorinating rubber in carbon tetrachloride solutions which contain more than 5 per cent of sulphur.<sup>75</sup>

French P. 766,289, 1934, to Soc. anon. des pneumatiques Dunlop; *Chem. Abs.*, 1934, 28, 7562. The liquid polychlorides of benzene have also been utilised as solvents, M. Polunkovskaya, *J. Rubber Ind. (U. S. S. R.)*, 1934, 11, 142; *Chem. Abs.*, 1934, 28, 7569.

Benzene may be used as the solvent and no difficulty encountered from the action of chlorine on it even when chlorination is conducted at temperatures near the boiling point of the liquid. In variations of the method, chlorination was accompanied by vulcanization with sulphur chloride or it was preceded by treatment with hydrogen chloride.<sup>76</sup> Hard rubber dust, after being freed from excess sulphur, yielded on chlorination a dark brown liquid.

Ellis and Boehmer<sup>77</sup> chlorinated vulcanized rubber by the application of pressure without the use of a solvent and obtained a product practically insoluble in benzene and considerably tougher than raw rubber similarly treated. The Deseniess and Nielsen<sup>78</sup> method of chlorinating raw rubber in boiling carbon tetrachloride was equally applicable to vulcanized rubber, as all of the sulphur was removed as sulphur chloride during the reaction.

Harries<sup>79</sup> has proposed a method of regenerating vulcanized rubber by treating it with hydrogen chloride. A thick, colloidal solution of rubber in xylene is saturated with hydrogen chloride and the rubber hydrochloride formed is then refluxed with pyridine or is added to fused sodium or potassium hydroxide. The regenerated rubber is oily, but polymerization causes it to increase in consistency on standing.

Products which are more soluble than ordinary chlorinated rubber have been made by Shadbolt<sup>80</sup> through treatment of the thermoplastic substances produced from rubber by the action of oxygenated phosphorus halides which contain more oxygen than the corresponding phosphorus oxyhalides. Even though many plasticizers may be mixed with the products, vegetable oils are incompatible.

#### USE OF CHLORINATED RUBBER AS A PAINT

Aside from use to a limited extent as a molding compound, the important application of chlorinated rubber has been in the field of lacquers and protective coatings.<sup>81</sup> The fact that inexpensive solvents can be employed has contributed to this development. The clarity and light color of the finished film and the low viscosity of solutions of relatively high concentration make its application for this purpose particularly desirable. A benzene solution containing as much as 20-30 per cent of highly chlorinated rubber has a good brushing consistency whereas a similar solution containing 6 per cent of crude rubber will scarcely pour.<sup>82</sup> The dried film from a chlorinated product of this kind is hard, tough, glossy and trans-

lucent with a light yellow color and exhibits a high resistance to the action of acids, alkalis and oxidizing agents.<sup>81</sup>

#### PROPERTIES OF CHLORINATED RUBBER PAINTS

Tornesit represents the first commercial recognition in the United States of the value of chlorinated rubber. The manufacture of Tornesit began in Germany at a place called Tornesch, near Hamburg. Later, an American concern,<sup>82</sup> after a

*Courtesy Hercules Powder Company*

FIG. 143.—Comparison of Tornesit (lower right) with Two Other Acid-Resisting Paints After Exposure for Two Years.

protracted investigation, embarked on the manufacture of Tornesit in the United States.<sup>83</sup> As a result of these tests Tornesit is considered to be "probably the most important development in the protective-coating industry since the discovery of nitrocellulose as a base for lacquers." Considered from the standpoint of commercial utility, it seems likely that no other film approaches Tornesit in resistance to acids, alkalis and the many other corrosive elements that are normally destructive to coatings. It gives to the paint manufacturer a material that can be formulated into both an acid- and alkali-resisting paint. Its general uses in protecting property against corrosion, weathering, water, steam, dust, fumes, gas, alkalis and acids become more widespread as its advantages become more generally known.<sup>84</sup>

<sup>81</sup> Chlorinated rubber has been placed on the market under the trade names "Duoprene" (United Alkali Co., I. Levinstein & Co., Imperial Chem. Ind., Ltd.), "Pergut" (I. G. Farbenind. A.-G.), "Tornesit" (New-York Hamburger Gummi-Waaren Compagnie, "Herold" A.-G.; Deutsche Tornesit-G.m.b.H., Hercules Powder Co.) and "Tegofan" (Tegofan G.m.b.H.).

<sup>82</sup> Hercules Powder Co., Wilmington, Del.

<sup>83</sup> License rights were secured by the Hercules Powder Co. from the German company and also from the Chadeloid Chemical Co., owners of the Ellis and Boehmer U. S. Patents

<sup>84</sup> For reports on Tornesit see D. R. Wiggam, W. Koch and F. Mayfield, *Ind. Eng. Chem., News*

Tornesit is practically odorless, non-inflammable and non-combustible. The specific gravity is about 1.5 and the product yields a bulking value, when put into solution, of 0.08 gallon per pound, which is about that of nitrocellulose. When Tornesit solution is poured on a glass plate and allowed to dry, a clear film similar to nitrocellulose results. The toughness of the film varies with the viscosity of the Tornesit used, but the grade useful in protective coatings is quite brittle and requires compounding with softening agents to impart the necessary flexibility.

Tornesit of widely differing viscosities may be prepared.<sup>87</sup> The 130-centipoise type is most useful in protective coatings, permitting spraying and brushing concentrations similar to those attainable with  $\frac{1}{4}$ -second nitrocellulose. The 130-centipoise viscosity was determined on a 20 per cent solution of Tornesit and toluene with the capillary viscosimeter at 25°C. This material closely parallels the viscosity of  $\frac{1}{4}$ -second nitrocellulose in a mixture of 50 per cent butyl acetate and 50 per cent toluene. For plastics or fabric coating, where greater toughness is desired, higher viscosity types are useful, but for adhesives lower viscosity grades are valuable.

#### SOLVENTS AND PLASTICIZERS OF CHLORINATED RUBBER PAINTS

Tornesit is insoluble in water, but dissolves readily in the common aromatic hydrocarbons (benzene, toluene, xylene), although completely insoluble in petroleum hydrocarbons.<sup>87a</sup> The chlorinated aliphatic hydrocarbons (ethylene dichloride and carbon tetrachloride), however, are good solvents. Tornesit is not soluble in either aliphatic or aromatic alcohols. Ethyl ether has a slight swelling action. On the other hand, ethylene glycol, glycerol diethyl ether and certain other ethers of glycerol<sup>88</sup> are good solvents. Ketones behave like ethyl ether in producing a swelling action. Along with the ethers, the ketones may be used as diluents to confer the special evaporation rate required of the solvent mixture. All of the common ester solvents may be used with Tornesit.<sup>89</sup> The terpene hydrocarbons are in general incompatible; on blowing with air, they become swelling agents and in some cases active solvents. Alkyl sulphides, sulfoxides, and sulphones are excellent solvents.

Table 57 indicates the types of softening agents which are especially useful:

<sup>87</sup> Tornesit solutions with viscosities of 30, 130 and 500 centipoises are commercially available.

<sup>87a</sup> See F. Kirchhof, *Chem.-Ztg.*, 1934, 58, 542; *Brit. Chem. Abs. B*, 1934, 774.

<sup>88</sup> Epiethylin and epiphenylin.

<sup>89</sup> Tests made on 25 cc. of 20% toluol solutions of Tornesit show that the following amounts of diluents will be tolerated before precipitation occurs: Union Solvent #8=26.7cc.; Union Solvent #20=75.0 cc.; Union Solvent #30=75.0 cc.; Union Solvent #40=150.0 cc.; Solvesso #1=31.0 cc.; V. M. & P. Naphtha=19.4 cc.

<sup>90</sup> The ethyl ester of hydrogenated abietic acid.

Tornesit was found to be compatible in films with the following substances<sup>a</sup> when both were dissolved in a mutual solvent, and a film was produced from this solution: raw castor oil, raw tung oil, bodied tung oil, pine tar, gas-house tar, rosin, ester gum, elemi, dammar, copals, amberols, cumarones, indenes and certain of the polyvinyls,<sup>b</sup> polyacrylins and bitumens.<sup>c</sup>

By the same method, the following materials were found to be less compatible or incompatible: bodied castor oil, rubber, Resoglas,<sup>d</sup> gilsonite, ethyl cellulose, benzyl cellulose, butyl cellulose, cellulose nitroacetate, asphalt, coal tar, Paraplex RG-2,<sup>e</sup> nitrocellulose, benzyl ether resin, vaseline, Nujol, vinylite resins and most of the phthalic anhydride resins tested.

#### FORMULATION OF CHLORINATED RUBBER PAINTS

Extraordinary adhesion is imparted to a Tornesit film by various plasticizers, a good combination being bodied tung oil and Hercolyn. Good adhesion also re-

sults from the incorporation of soft resins and pigments into plasticized Tornesit films. It has been determined, however, that, in general, most resins in Tornesit formulations accelerate checking of the film and appear to have no useful purpose beyond increasing the total solids of the paint.

A film formed from a simple toluene solution of Tornesit is brittle and has

<sup>a</sup> The addition of polyvinyl resins is said to increase the adhesive power and the fastness to light. G. Schultze, U. S. P. 1,980,959, Nov. 13, 1934, to I. G. Farbenind. A.-G.; *Chem. Abs.*, 1935, 29, 530. Nevinol is reported (E. R. Coyle, *Drugs, Oil and Paints*, Aug. 1935) to be a good plasticizer for chlorinated rubber coatings, e.g., Tornesit, imparting flexibility and resistance to water, alkalies and acids. The plasticizer is an oily, high-boiling polymer, apparently obtained from coal-tar naphtha.

<sup>b</sup> Also Dulux R. C. 119 & 120, Bakelite XR 4406, Rezyl 1103 and sulphurized aromatic hydrocarbons, French P. 784,471, 1934, to I. G. Farbenind. A.-G.; *Chem. Abs.*, 1934, 28, 6002. See Chapter 50, for a discussion of the last type of compound.

<sup>c</sup> A polystyrene resin.

<sup>d</sup> An alkylid resin.

•poor adhesion, although it has great chemical resistance. As outlined above, flexibility and adhesion can be obtained without sacrificing chemical resistance by proper selection of plasticizers from the list of compatible materials.

Unpigmented Tornesit films, like clear nitrocellulose lacquer, break down under direct outdoor exposure. A 100 per cent Tornesit film compared with a nitrocellulose-dammar film, by exposing both through glass to ultraviolet irradiation, showed that the discoloration of the Tornesit film was no greater than the nitrocellulose-dammar film. Clear films, however, serve many useful purposes indoors, because the chemical resistance of Tornesit is greater than most resins and pigments used in the compounding of paint.

The more important field for Tornesit is in pigmented products. A fairly wide range of pigments has been used in Tornesit films for outside and specialty paints. Those actually tested include zinc oxide, lithopone, Titanox, carbon black, bone pitch, oil black, chrome yellow, chrome green, Prussian blue, toluidine red and various grades of iron oxide and red lead. Of these, Prussian blue, chrome green, chrome yellow, red lead, and lithopone fade and discolor considerably. Bone pitch does not produce gas, as it does in nitrocellulose lacquers. Paints with these pigments have been exposed to weathering conditions for more than two years and results have shown excellent protection for the metal, and the films can be polished to a good surface. Coatings pigmented with toluidine red showed the least amount of fading and, in general, gave best results.

<sup>97</sup> Hydrogenated ethyl abietate.

<sup>98</sup> Sold under the name "Sulpho-Terpoil."

In Table 58 are some of the paint formulations in which Tornesit has been used satisfactorily. The general primer, which is given first, is employed as an undercoat for the various finishes which follow it in this table.

As indicated one of the most outstanding characteristics of Tornesit paints is their great resistance to corrosive influences.<sup>98</sup> Not only is usual protection afforded steel against rusting but, because of the chemical inertness of chlorinated rubber, Tornesit paints, when properly made, exhibit striking resistance to 50 per cent ammonium nitrate solution, 5-50 per cent sodium hydroxide, 5-70 per cent sulphuric acid, 85 per cent phosphoric acid, 10 per cent hydrochloric acid, 10 per cent nitric acid, organic acids, such as 5-80 per cent lactic, bleach solutions, and corrosive gases, such as chlorine, sulphur dioxide and ammonia.

The various properties of Tornesit as outlined above indicate a wide field of utility in protective coatings. These include non-inflammable smoke-, acid- and alkali-resistant paints for structural steel, ships and concrete. Among the other fields of application are the impregnation of fabric and paper, electrical insulation and the preparation of adhesives and plastic bodies.

Another item of interest is that concerning the electrical properties<sup>99</sup> of Tornesit films. Clear Tornesit has dielectric properties equal to or better than those of any other protective coating. Dielectric strength is retained even in the presence of moisture. Plasticized Tornesit films are also very efficient in this respect insofar as they have been tested. The lowering of the dielectric strength depends on the type and particle size of the pigment added, small particle size being most satisfactory.

The following are some of the values determined:

Power factor at 1000 cycles . . . . .	0.003
Dielectric strength (4 mil sheet) . . . . .	2300 volts per mil
Arcover test (discharge before breakdown) . . . . .	Good
Surface resistivity (24°C., 85% relative humidity) . . . . .	$2 \times 10^{13}$ ohms

Because of its corrosion-resistance chlorinated rubber has been used to coat iron pipes placed underground.<sup>100</sup> The resistance of chlorinated-rubber films to various reagents has been found satisfactory by many investigators.<sup>101</sup> Some, however, have not been so favorably impressed with the properties of chlorinated rubber.<sup>102</sup>

Rosenthal and Schultze,<sup>103</sup> who found that all samples of chlorinated rubber are not equally resistant, proposed two tests for the evaluation of these products. One involves heating a solution of the material to be tested in an oil bath at 100°C. and noting the time required for a strip of congo paper 5 cm. above the liquid to turn cornflower-blue. The other is more difficult to apply since it depends on

<sup>98</sup> After three years of exposure on a test fence in Wilmington, Delaware, steel panels coated with Tornesit paints were well protected, and the metal was still bright and free from rust under the paint. Abs.*, 1933, 27, 4953. *Chem. Industries*, 1933, 33, 506) and E. Karsten (*Kautschuk*, 1933, 9, 41; *Chem. Abs.*, 1933, 27, 4126). Replies to Krumbhaar have been made by F. C. Dvche-Teague (*Oil and Color Trades J.*, 1933, 1623). J. B. Serreston (*ibid.*), and C. A. Redfern (*Rubber Age*, 1933, 34, 113; *Chem. Abs.*, 1934, 28, 1889); they have found that chlorinated rubber is entirely satisfactory. Investigations carried out in the author's laboratory have shown that chlorinated rubber has excellent properties and is one of the best flexible resistant materials yet encountered.

<sup>104</sup> L. Rosenthal and G. Schultze, *Farben-Chem.*, 1934, 5, 53. Reviewed in *Synthetic and Applied Finishes*, June, 1934, 5, 65; *Chem. Abs.*, 1934, 28, 3618. See also Schultze, *Gas u. Wasserfach*, 1935, 78, 68; *Chem. Abs.*, 1935, 29, 2373.

having films of equal thickness. The test consists in measuring the degree to which a polished copper plate coated with the chlororubber turns dark when exposed to a mercury-arc. When paints are made from chlororubber of good stability and when properly pigmented and plasticized, these paints are durable and should find extensive application where protective coatings resistant to severe chemical, mechanical and atmospheric influences are required. Rosenthal and Schultze agreed with Krumbhaar<sup>104</sup> that the unpigmented films are sensitive to light. Gardner and Stewart<sup>105</sup> reported similar results with pigmented and clear varnishes. Another investigator noting differences existing between samples of

chlorinated rubber was Merz,<sup>106</sup> who found that the proportion of hot-water-soluble chlorine varied greatly.

It has already been stated that chlorinated rubber decomposes at about 150°C. Rinse<sup>107</sup> reported that, at 100°C., the loss of weight is still less than 5 per cent after 400 hours. The loss in weight from a film deposited by evaporation of a chloroform solution may be due to hydrochloric acid and residual chloroform.<sup>108</sup> The tendency to occlude traces of solvents has been noticed both by Rosenthal and Schultze<sup>109</sup> and by Jordan.<sup>110</sup> Because of this property, solvents boiling higher than xylene should not be used unless the coating is to be baked. Rosendahl<sup>111</sup> reported that no hydrogen chloride was evolved during exposure to ultraviolet light even after 17 days.

Mention has already been made of the fact that the use of various plasticizers is sometimes desirable to increase the flexibility and adhesion of chlorinated rubber

films. Clear unpigmented films have at times a tendency to leave white spots on drying; this can be eliminated by the use of resins, camphor, triphenyl phosphate and trieresyl phosphate, which act as plasticizers.<sup>112</sup> Diethyl phthalate, pentachloroethane<sup>113</sup> and sulphonalkylamides of aromatic hydrocarbons<sup>114</sup> improve the flexibility. Since cumarone resin is not readily attacked by acids and alkalies, it may be added to increase the concentration of the coating solution without materially affecting the viscosity.<sup>115</sup> Such a mixed lacquer has been found to be particularly applicable as a coating for concrete.<sup>116</sup>

Other plasticizers which are stable to hydrolyzing agents are the chlorinated biphenyl compounds,<sup>117</sup> alkylated polynuclear aromatic hydrocarbons<sup>118</sup> and hydrogenated alkyl or aralkyl esters of abietic acid.<sup>119</sup> Phthalic acid esters when mixed with chlorinated rubber gave very hard surfaces and were highly resistant to the action of motor fuels.<sup>120</sup> Neutral suint and chlororubber have been proposed as a composition for the initial coating of porous objects before painting.<sup>121</sup> A transparent, waterproof material can be prepared from chlorinated rubber, a wax (paraffin, carnauba and montan wax) and dibutyl phthalate.<sup>122</sup>

Various drying oils have also been used as plasticizing agents, producing oil varnishes. In the customary method of making an oil varnish, the resin is melted to increase its solubility, hot oil is admixed, whereupon thinner is added. Since chlorinated rubber may decompose when heated to temperatures above 150°C., it is incorporated by mixing in solution with the oil, either cold or at a temperature not above 100°C., the solvent serving to replace part of the thinner otherwise required in the varnish.<sup>123</sup> The addition of chlorinated rubber decreases the permeability of a boiled linseed oil to sulphur dioxide, hydrogen chloride and ammonia.<sup>124</sup> When a small amount of linseed oil (1-3 per cent) is added a dull or flat finish is obtained.<sup>125</sup> Larger amounts of drying oils, for example from 40 per cent up to equal proportions based on the weight of dry chlorinated rubber, gave a varnish drying to a bright, glossy surface.<sup>126</sup>

To avoid turbid solutions of tung oil and chlorinated rubber that dry to frosted or dull films, Boehmer<sup>127</sup> suggested the selection of the two materials on the basis of the amount of chlorine combined with the rubber and the degree of polymerization of the oil. As the chlorine content of the rubber increased, the oil required more cooking in order that clear solutions might be obtained. A well-boiled oil, of course, dries more rapidly than raw oil and a highly chlorinated rubber is more

<sup>127</sup> N. Boehmer, U. S. P. 1,635,812, July 12, 1927, to Chadeloid Chemical Co.; *Chem. Abs.*, 1927, 21, 2992.

soluble than one of lower chlorination. Proper treatment of the two materials therefore results in a very satisfactory film.

A varnish of this type, yielding a smooth, glossy finish, was made up as follows: 25 parts of chlorinated rubber, containing approximately 67 per cent of combined chlorine, were dissolved in 50 parts of solvent naphtha and 75 parts of prepared tung oil. The latter was made by cooking the raw oil for 45 minutes at 200°C. with about 12 per cent of limed rosin. The mixture was then thinned with turpentine and solvent naphtha to the proper consistency and allowed to stand to precipitate foreign matter. Aliphatic hydrocarbons of the benzine type tend to decrease the solubility of chlorinated rubber and therefore could not be present in large proportions as thinners. A film of this material dried dust-free in 2 hours and was hard, tough, clear and glossy when thoroughly dry. The proportion of oil can be varied to meet particular needs and other drying oils may be added to the varnish.

The use of a smaller proportion of tung oil leads to the production of a quick-drying varnish.<sup>128</sup> Thus, highly chlorinated rubber, dissolved in toluene or solvent

*Courtesy Hercules Powder Company*

FIG. 146.—Four Cylindrical Tanks Protected against Sulphuric and Nitric Acid Fumes by Spraying with Tormesit Paint.

naphtha, was mixed with 10 per cent of its weight of tung oil to produce a composition that dried quickly to a clear, tough, non-inflammable film. This mixture could be employed for ordinary varnishing purposes, as well as for coating concrete or as an acid- and alkali-resistant varnish. Waxes (paraffin, ceresin or beeswax) incorporated in the solution gave a flatting varnish.

According to Geer,<sup>129</sup> vegetable oils (rapeseed, linseed, tung or corn oil) may be added to a solution of chlorinated rubber and the oil oxidized or vulcanized in the solution by sulphur chloride or by heating with sulphur. The material is useful as an acid- and alkali-resistant coating and as a covering for balloon fabrics. After hardening with heat it can be used as a substitute for celluloid and ebonite. In a coating composition described by Bradley and Gibbons,<sup>130</sup> chlorinated vulcanized rubber was dissolved in a mixture of a low-boiling and a high-boiling solvent (benzol and solvent naphtha) to give a low-viscosity varnish or paint. Such pigments as sublimed white lead, titanium oxide, ultramarine and toluidine toner were utilized to obtain colored enamels.

The color of solutions of chlorinated rubber may be improved by bleaching

<sup>128</sup> Carleton Ellis, U. S. P. 1,695,638, Dec. 18, 1928, to Chafeloid Chemical Co.; *Chem. Abs.*, 1929, 23, 999.

with fuller's earth<sup>121</sup> or oil-soluble dyes may be added to give a colored lacquer.<sup>122</sup> Both the acidity and turbidity can be eliminated in chlorinated rubber paints by the use of quicklime, sodium carbonate or marble dust to neutralize the acid while calcium chloride can be employed to remove water.<sup>123</sup> Schmidt and Deseniss<sup>124</sup> mixed into the varnish of chlorinated rubber pulverized carborundum or quartz of grain size 40-100 microns. This improved the adherence to smooth surfaces and also the resistance to shock and abrasion.

Solutions of chlorinated rubber have been suggested for sealing bottles. The neck of the stoppered container is immersed into the solution a number of times until a film of sufficient thickness is formed; the chlororubber is then precipitated by dipping into alcohol and is dried.<sup>125</sup> Van Heuckeroth<sup>126</sup> stated that a solution of chlorinated rubber is a satisfactory vehicle for calcium sulphide in luminous paints.

### MOLDINGS

Some of the earliest investigators in the field, for example Engelhard, Havemann and Day,<sup>127</sup> proposed that dry chlorinated rubber be used as a molding compound. This was one of the uses which Dyche-Teague<sup>128</sup> also suggested for chlorinated rubber. Ostromislensky<sup>129</sup> mixed crude rubber on a rubber mill with chlorinated or brominated rubber in the proportion of 7-85 parts of the halogen-treated rubber to 10 parts of crude rubber. Heating the mixture in a press was stated to "vulcanize" it to an ebonite-like mass.

Latex can be utilized in making a molding composition. Halogens or halogen acids normally tend to coagulate latex and unless steps are taken to prevent the formation of a solid mass the batch cannot be readily chlorinated. The procedure is as follows: 100 parts of kieselguhr were moistened with 150 parts of water to which had been added 9 parts of concentrated ammonium hydroxide (to prevent coagulation of the latex subsequently used). Then 100 parts of latex, containing 36 per cent of solids, were added and the mixture stirred until homogeneous. Excess water was removed and the dried mass was subjected to the action of chlorine gas until no more was absorbed. Hydrogen chloride formed during the reaction was neutralized with ammonia and the material was washed and dried. The product could then be molded by pressing for 10 minutes at 115°C. forming a hard material which could be polished to a high luster. It was not affected by water, oils or gasoline.<sup>130</sup>

A thermoplastic molding compound may be obtained by mixing chlorinated rubber with a phenol-aldehyde condensation product.<sup>131</sup> A solution containing 1 part of rubber was treated with chlorine until the rubber had absorbed twice its weight of chlorine. To this solution were added 2 parts of phenol and 2 parts of a 40 per cent solution

of formaldehyde and the mixture was boiled under reflux for 2 hours. The material was washed with hot water, worked on a cold rubber mill to expel water, then ground and dried. The dry powder was thermoplastic and could be molded at a pressure of 3000-4000 pounds per square inch at a temperature of 175°C. The molded article was hard, opaque and would receive a bright finish from a polished mold. It was insoluble in acids and alkalies and resistant to electrical currents. Chlorinated vulcanized rubber could be substituted for chlororubber,<sup>142</sup> and the resulting composition used for bonding abrasive materials.<sup>143</sup> A similar reaction product between phenol and chlorinated rubber has been recommended for painting ship bottoms.<sup>144</sup>

A water-resistant insulating material was made by Plauson<sup>145</sup> by adding urea to fused chlorinated rubber and treating the mixture with formaldehyde. Its properties could be varied by the addition of natural resins or resin oils.

Chlorinated rubber, after softening to the form of a gel with carbon disulphide, can be extruded to form a silk-like fiber.<sup>146</sup> The solvent is removed by evaporation or by leading the extruded fiber into alcohol, acetic acid or gasoline. Plasticizers make the fiber more flexible. The thread has a fair luster, is noninflammable and can be woven into a web or fabric. Colored fibers are obtained by adding a dye to the gelled mass.

#### MISCELLANEOUS OTHER USES OF HALOGENATED RUBBER

The properties of halogenated rubber have suggested several other uses. For instance, since it only chars and does not burn when held in the flame it has been proposed as a fire-retarding insulator.<sup>147</sup> Deseniss and Nielsen<sup>148</sup> mixed chlorinated rubber with tar, asphalt and other bituminous substances and employed the resulting product as an insulator on metal pipe. Finely ground asbestos may also be added to such a mixture. Chlorinated rubber has even been advocated as an addition to the bituminous materials used in road construction.<sup>149</sup>

Warner<sup>150</sup> made an adhesive from brominated rubber for uniting rubber to metal. A solution of chlorinated rubber has been described as an adhesive for paraffined paper.<sup>151</sup> When these solutions of chlorinated rubber contain a large proportion of solids, they can be used as cements.<sup>152</sup> The flexibility of such cements is increased by the addition of softeners such as camphor, triphenyl and tricresyl phosphates, or semi-drying oils, e.g., corn or peanut oil.<sup>153</sup> Incorporation of extending agents is useful in overcoming shrinkage. Examples of agents of this type are whiting, zinc oxide, barytes, litharge, silex, asbestos, talc and organic materials such as cotton wool and wood flour.

Cottonseed oil, which has been treated with chlorine at an elevated temperature until the oil has increased 30 per cent in weight, is a solvent for chlorinated rubber. When this oil is added to a solution of chlorinated rubber in carbon tetrachloride and the latter evaporated, the product is stated to be a coating material for fly paper<sup>154</sup> or may be added to varnishes to improve their elasticity.<sup>155</sup> Chlorinated drying and semi-drying oils have also been employed with chlororubber in rubber compositions.<sup>156</sup>

Ellis<sup>157</sup> impregnated or coated fabrics and paper with chlorinated rubber to make them fire-resistant,<sup>158</sup> a property depending to some extent on the degree of chlorination and the thickness of the coating. Such coatings are also waterproof

ing aqueous emulsions of chlorinated rubber dissolved in organic solvents or mixed with drying oils.<sup>161</sup>

Chlorinated rubber may also be applied in preparing paper filter packs for edge filtration,<sup>162</sup> in treating airplane wings<sup>163</sup> or rubber-impregnated filter cloths,<sup>164</sup> in printing designs on raw pasteboard,<sup>165</sup> and in manufacturing artificial leather by binding together comminuted cork and fibers.<sup>166</sup>

Since halogenated rubber is adequately resistant to oxidation and does not swell in the presence of water and many solvents it has found use as a facing or lining material. Arnold<sup>167</sup> made a printer's blanket which had a top layer of chlorinated rubber. Garvey<sup>168</sup> protected soft vulcanized rubber with a coat of chlorinated rubber. The method suggested was to subject the rubber to the action of chlorine and then to apply a solution of chlorinated rubber and o-nitrodiphenyl ether. The surface of rubber-covered cloth is made hard and smooth by treatment with a heavy metal salt of a fatty acid, followed by halogenation.<sup>169</sup> Twiss and Jones<sup>170</sup> hardened the surface of golf balls by the action of chlorine. Bales of rubber were protected from oxidation through bromination of their surfaces.<sup>171</sup> Further applications of chlororubber include uses as a stuffing for pillows,<sup>172</sup> as an ingredient in chewing gum<sup>173</sup> and to assist in the hot cure of Thiokol.<sup>174</sup>

Chlorinated gutta-percha solutions are less viscous than those of chlorinated rubber of corresponding concentration. They can be used as lacquers and form bright, hard, though somewhat brittle films. The brittleness may be modified by the addition of softeners, and natural and synthetic resins may also be added. Ellis reported that the films offer excellent resistance to the action of acids and alkalis.<sup>175</sup>

## Chapter 56

### Resins from Halogenated Compounds

There are two large classes of resins produced from halogenated compounds. The first class includes high-molecular-weight substances resulting from inter-molecular condensations with the elimination of halogen or hydrogen halide. The second class consists of the halogenated products which owe their amorphous and resinous properties to the fact that they are mixtures of several individuals, as for example, the chlorinated biphenyls and naphthalenes. These two classes of resins will be taken up in order.

#### CLASS I. CONDENSATION RESINS

Resin-like substances are formed by treating compounds of the type of benzyl chloride, benzal chloride, xylene dichloride, benzotrichloride or the naphthalene chlorides with metal halides (Friedel-Crafts reaction), with metals such as zinc, copper or nickel (Zincke reaction), or by the action of alkali metals on poly-halogenated hydrocarbons (Würtz-Fittig synthesis). In general such resins do not contain chlorine (or other halogens), as it is eliminated in the resin-forming reaction.

**Aralkyl-Halide Resins.** The Friedel-Crafts reaction is a fruitful source of tars and resins which are often the chief product in the case of a polyfunctional reactant like benzyl chloride which contains an aromatic nucleus and an alkyl halide residue in the same molecule. Böeseke<sup>1</sup> declares that this compound is not suitable for use in the Friedel-Crafts reaction if products of a definite composition are desired. On adding aluminum chloride to benzyl chloride, hydrogen chloride is evolved and a complex mixture of hydrocarbon polymers formed, the major portion of which are insoluble in all solvents.<sup>2</sup> The polymers have the empirical formula  $(C_7H_6)_n$ , and probably consist of macromolecules<sup>3</sup> made up of the group  $-C_6H_4CH_2-$ .<sup>4</sup>

Ferric chloride acting on benzyl chloride in the cold transforms the latter into a soluble, chlorine-free resin.<sup>5</sup> To 100 parts of benzyl chloride, 0.5 part of anhydrous ferric chloride is added while the mixture is stirred. Soon a vigorous evolution of hydrochloric acid begins and progresses regularly for a considerable period. The temperature increases only slightly. A dark brown, porous solid is formed, which is blown with steam to separate any unchanged benzyl chloride

<sup>1</sup> J. Böeseke, *Rec. trav. chim.*, 1904, 23, 98; *J.C.S.*, 1904, 86 (1), 384.

<sup>2</sup> W. H. Perkin and W. R. Hodgkinson, *J.C.S.*, 1880, 37, 721. C. Friedel and J. M. Crafts, *Bull. soc. chim.*, 1885, 43, 53. J. Schramm, *Ber.*, 1893, 26, 1706; *J.C.S.*, 1893, 64 (1), 561.

<sup>3</sup> It is possible that each molecule contains a chlorine atom at the end of the chain but in large molecules of this nature the percentage of chlorine would be very low and could not be determined accurately on account of the difficulty of purification. That chlorine is probably present is borne out by the work of E. Wertyporoch and A. Farnik (*Ann.*, 1931, 491, 265; *Chem. Abs.*, 1932, 26, 1275) who treated benzyl chloride in nitrobenzene solution with aluminum chloride at  $-15^\circ C$ . and isolated o- and p-chloromethyldiphenylmethane,  $C_6H_4CH_2-C_6H_4CH_2Cl$ , which can be considered the initial stage in the formation of the polymeric chain.

<sup>4</sup> R. A. Jacobson, *J.A.C.S.*, 1932, 54, 1513. Böeseke (*loc. cit.*) considered the fundamental group to be  $C_6H_4CH_2-$ .

<sup>5</sup> German P. 280,595, 1913, to Badische Anilin- & Soda-fabrik; *J.S.C.I.*, 1915, 34, 500.

and is then ground and washed with hydrochloric acid to remove ferric chloride. A yellowish resin is obtained, soluble in benzene, carbon tetrachloride, chloroform, cyclohexanone, cyclohexanol acetate and various other vehicles but insoluble in aliphatic alcohols, ketones and hydrocarbons. Solutions of the resin may be used for varnishing, and the coatings are resistant to acids and alkalis. Warm caustic soda solution of 35 per cent concentration does not attack the film.\* Ushakov and Kon' believe that benzyl-chloride resin will find industrial applications as a shellac substitute. According to Jacobson,<sup>8</sup> the resin is not compatible with nitrocellulose, cellulose acetate, polyvinyl acetate, polyvinyl chloride, drying oils or alkyd resins.

Zirconium tetrachloride has been suggested as a condensing agent for benzyl chloride in carbon disulphide solution to give a resin applicable as a shellac substitute. The resin thus prepared may be mixed with other resins, rubber, or gutta-percha.<sup>9</sup>

To summarize the effect of different catalysts in the condensation of benzyl chloride, it may be noted that polymerization in the presence of aluminum chloride furnishes an insoluble hydrocarbon polymer,  $(C_7H_8)_n$ , and a small amount of a soluble resin of the same empirical formula. If ferric chloride is used the yield of soluble resin increases at the expense of the insoluble polymer. With stannic chloride only the soluble resin is formed.<sup>10</sup> Jacobson found the molecular weight of the soluble resins to be about 2000. The insoluble polymers presumably have much higher molecular weights.

A mixture of  $\alpha$ - and  $\beta$ -chloromethylnaphthalene, dissolved in carbon bisulphide and treated with aluminum chloride, yields an elastic, brown, rubber-like substance insoluble in benzene. When  $\beta$ -chloromethylnaphthalene alone is employed very little resin is formed.<sup>11</sup>

Phenylethyl chloride is condensed by the action of aluminum chloride to a chlorine-free, tough, reddish mass, insoluble in most solvents.<sup>12</sup> This product may be represented as made up of the group  $-C_6H_5-CH_2CH_2-$ .

Zincke<sup>13</sup> permitted copper, silver and other metals to react on benzyl chloride. Onufrowicz,<sup>14</sup> who also studied the reaction between benzyl chloride and copper, obtained a resin when he heated the mixture in a sealed glass tube at a temperature of 150-160°C. When equal quantities of benzyl chloride and copper were heated (at this same temperature) for two hours in an open vessel, evolution of hydrogen chloride occurred accompanied by the formation of a thick liquid boiling between 110-360°C. and a tough resinous mass. The latter was soluble in benzene but only slightly so in alcohol. Evaporation of a benzene solution of the resin yielded a tough, yellow fluorescent body. At lower temperatures (100-140°C.) and in an atmosphere of dry carbon dioxide, hydrogen chloride was given off at 107°C. and only a liquid product secured.

According to Gladstone and Tribe,<sup>15</sup> a zinc-copper couple converts benzyl bromide into a resinous mass which is partly soluble in ether or benzene. The ether-soluble portion is a brittle, transparent, yellowish red resin melting at 42°C. Analogous results were obtained with benzyl chloride.

Prost<sup>16</sup> found that upon mixing zinc dust and benzyl chloride below the boiling

point of the benzyl chloride he obtained a viscous product which could be distilled up to 340°C. From the distillate he isolated benzyl chloride, bibenzyl and toluene. The material boiling above 340°C. contained anthracene and a substance which appeared to be identical with the hydrocarbon  $C_{20}H_{18}$  found by Weber and Zincke.<sup>17</sup> At higher reaction temperatures, the result was a hard brown substance.

On heating benzyl chloride in a benzene solution with aluminum chips, Radziewanowski<sup>18</sup> observed that in addition to diphenylmethane, a large quantity of tarry material was formed. Nickel at a high temperature causes formation of the insoluble polymer of benzyl chloride.<sup>19</sup> Mailhe<sup>20</sup> obtained a yellow, voluminous mass on passing benzyl chloride vapor and hydrogen over hot nickel. Boiling benzyl chloride and magnesium react, according to Schorigin, Issagulianz and Gusseva, to give a glassy mass.<sup>21</sup>

Besides metals and metal chlorides, other catalysts have been suggested. Freund and Jordan utilized various surface catalysts, e.g., hydrated aluminum or magnesium silicates, kaolin, fuller's earth or silica.<sup>22</sup> In the attempt to improve the yield of monoalkyl ether of xylylene glycol, Quelet<sup>23</sup> heated 1',4'-dichlorodimethylbenzene with potassium hydroxide in dilute alcohol. An insoluble, yellow, condensation product resulted. A similar by-product is obtained in the preparation of 1',4'-dicyanodimethylbenzene from the corresponding dibromo derivative.<sup>24</sup>

**Aralkyl Halides and Hydrocarbons.** Although, as shown above, benzyl chloride forms resins of high molecular weight which may be either soluble or insoluble depending upon the extent of reaction and the particular catalyst, the inclusion of phenols or aromatic hydrocarbons such as naphthalene, anthracene, phenanthrene and various other coal-tar hydrocarbons, leads to soluble substances of relatively low molecular weight. The effect of these added substances is to limit the growth of the molecule so that it does not attain such a size that the product is insoluble. One example of this is the reaction of benzyl chloride with benzene in the presence of thallium trichloride and ferric chloride. The first was studied by Stadnikov and Kashtanov<sup>25</sup> who isolated diphenylmethane and p-benzylidiphenylmethane. The second was studied by Wertyporoch, Kowalski and Roeske,<sup>26</sup> who obtained triphenylmethane, two oils and a resin, in addition to diphenylmethane.

Condensation of benzyl chloride with methylnaphthalene in the presence of iron yields an odorless oil.<sup>27</sup> Impregnating agents, coatings and plastic insulating masses have been prepared from the condensation products of aralkyl halides on tar oil or its constituents.<sup>28</sup> An oil also was obtained when xylyl chloride and naphthalene were heated in an iron kettle for several hours at 100°C. Although the reaction has been stated to occur when the aralkyl halide and polynuclear hydrocarbon are heated together in absence of a catalyst,<sup>29</sup> Ushakov and Kon<sup>30</sup>

maintain that catalysts are indispensable since they failed to detect any reaction in their absence. Marschall<sup>31</sup> found that the presence of gaseous hydrogen chloride caused reaction to proceed at a low temperature.

Passing air through a suspension of manganese dioxide or ferric chloride in the oily condensation products from aralkyl halides and aromatic hydrocarbons produces harder materials.<sup>32</sup> A similar result is obtained by treating the oils with formaldehyde in conjunction with zinc chloride.<sup>33</sup> These hardened resins are readily soluble in aromatic hydrocarbons and linseed oil. Also they are stable towards light and resistant to water and alkalies. Other synthetic resins (phenol-formaldehyde, phenol-sulphur chloride and cumarone) may be hardened and made more soluble in hydrocarbons and linseed oil by treatment with benzyl chloride in presence of aqueous alkalies.<sup>34</sup>

A water-soluble condensation product is obtained by heating benzyl chloride with a solution of naphthalene sulphonic acid in sulphuric acid. Alternatively, a simple benzyl-halide-naphthalene resin may be prepared and then sulphonated with chlorosulphonic acid or oleum. Dichlorodihydronaphthalene can be used instead of benzyl chloride.<sup>35</sup>

Aralkyl chlorides also may be condensed with partly hydrogenated aromatic hydrocarbons. Dihydronaphthalene and dimethylbenzyl chloride heated to 200°C. (with a small proportion of zinc), or rosin and isopropylbenzyl chloride heated under reflux with ferric chloride, form resins which are soluble in linseed oil and in aliphatic hydrocarbons, but insoluble in alcohols.<sup>36</sup> Diphenylchloromethane and thiophene are condensed by the action of stannic chloride and form a resinous mass.<sup>37</sup>

Kränzlein and Voss made neutral resins by esterifying the condensation products initially formed from resins and aralkyl halides.<sup>38</sup> For example, 160 parts of colophony were mixed with 40 parts of benzyl chloride and warmed slowly. A little above 100°C. the evolution of hydrogen chloride began. If desired, the reaction could be hastened by the addition of 0.2 part of zinc chloride. After the evolution of gas subsided, the mass was heated to 200-210°C. and held there for an hour during which it was stirred. It was then cooled to 100°C. and 15 parts of glycerol and 50 parts of xylene added. After heating at 240-250°C. for 4 hours and removing the volatile substances under reduced pressure, a light-colored resin was obtained. It was soluble in hydrocarbon solvents, but not in aqueous alkalies. It had good elasticity and resistance to the weather. Other alcohols which may be substituted for glycerol are glycol and benzyl alcohol. In several cases the aralkyl halide employed was prepared by the action of 40 per cent formaldehyde and hydrochloric acid on xylene, diphenyl oxide or anisol.<sup>39</sup>

Makarov and Andrianov<sup>40</sup> report that casein and benzyl chloride react in the presence of alkalis to form resins. Kirchhof<sup>41</sup> has studied the action of benzyl chloride on rubber using aluminum chloride as a catalyst. White to yellow, easily pulverized, thermoplastic products were formed. They were inert to alkalies and acids (other than nitric acid) and had good insulating properties.

**Aralkyl Halides and Phenols.** Condensation between benzyl chloride and phenolic compounds forms resins whose properties are dependent upon the phenolic body used. In general the resins formed from phenols and aralkyl chlorides are soluble in alcohols, whereas those from aromatic hydrocarbons and aralkyl chlorides are insoluble in alcohol. One mol each of phenol and benzyl chloride are heated without a catalyst on an oil bath (reaction begins at 130°C. and is completed by slowly raising the temperature to the boiling point of benzyl chloride), until the evolution of hydrochloric acid ceases, yields a clear, bright brown, thinly fluid oil which is soluble in dilute caustic soda solution.<sup>42</sup> An excess of phenol and zinc (as a catalyst) furnishes p-hydroxydiphenylmethane.<sup>43</sup> On the other hand, when equal parts of benzyl chloride and phenol were heated in the presence of franconite a plastic mass resulted.<sup>44</sup>

Chloromethylnaphthalene condenses with phenol to form a hard resin which is soluble in drying oils.<sup>45</sup> Benzyl chloride and  $\alpha$ -naphthol yield a thick, brown oil.<sup>46</sup>

Phenolic acids and their derivatives may also be reacted with benzyl and other aralkyl halides.<sup>47</sup> Many catalysts may be used including zinc, aluminum, iron, their halides and fuller's earth. The resinous materials are soluble in linseed oil, tung oil and turpentine and so may be employed in making varnish.<sup>48</sup> Among the combinations that have been suggested are dimethyl benzyl chloride with salicylic acid, dimethyl benzyl chloride with phenyl salicylate, dimethyl benzyl chloride with acetyl salicylic acid, isopropyl benzyl chloride with salicylic acid and 1,2,3,4-tetrahydro-6- $\omega$ -chloromethylnaphthalene with 2-hydroxy-3-methylbenzoic acid.

Resins from aralkyl halides and phenols are rendered soluble in water by sulphonation.<sup>49</sup> Doser and Thauss<sup>50</sup> made water-soluble substances by sulphonating the reaction products of aralkyl halides with rosin and phenols. For example, a resin was prepared by mixing 30 parts of rosin and 10 parts of phenol in the presence of 1.5 parts of 60° Be. sulphuric acid and heating to 70-80°C. for 8 hours. Then, 10 parts of this resin was treated at 110-120°C. with 3 parts of benzyl chloride and 0.2 part of zinc chloride. The final product was sulphonated with 2 parts of 100 per cent sulphuric acid. The original phenol-rosin resin can

be sulphonated before condensation with benzyl chloride. Likewise, phenol sulphonic acids may be condensed with aralkyl halides.<sup>61</sup>

**Benzal-Halide Resins.** Benzal chloride is very sensitive to resinification. Dissolved in carbon disulphide and treated with aluminum chloride, it forms a hard, insoluble product even at low temperatures.<sup>62</sup> Iron carbonate reacts vigorously with benzal chloride at 60°C. with formation of a black resinous mass,<sup>63</sup> and zinc oxide at 100°C. produces large quantities of tar unless a solvent is present.<sup>64</sup> On addition of zinc dust, a mixture of benzal chloride and aniline forms 4,4'-diaminotriphenylmethane and much resin.<sup>65</sup>

Condensation of benzal chloride or xylene dichloride with naphthalene, phenanthrene or anthracene yields resins which are hard in comparison with the oily products obtained from a mixture of benzyl chloride and polynuclear hydrocarbons. Iron may be used as a condensing agent.<sup>66</sup> The resins are readily soluble in hydrocarbon solvents and have been recommended as impregnating and coating agents,<sup>67</sup> or mixed with cellulose ethers to form plastic masses.<sup>68</sup> To make the resins still harder, they may be treated with formaldehyde<sup>69</sup> or blown with air<sup>70</sup> as was the case with the oily products from benzyl and xylyl chlorides.

Resins are obtained when benzal chloride is heated with either phenol, in the presence of zinc chloride at 50-100°C., or with m-cresol, in the presence of aluminum chloride at 70°C., until hydrogen chloride is no longer evolved, and the excess phenol or cresol is removed by steam distillation. An odorless, light-colored resin, which is soluble in caustic alkalis, alcohols and chloroform is produced. Similar products result from homologues of benzal chloride or from derivatives containing halogen in the nucleus.<sup>61</sup> Mackenzie<sup>62</sup> used 55 g. of phenol with 16.9 g. of benzal chloride without a catalyst. Heating the mixture gently at first and then gradually raising the temperature to 120°C. for 10 hours, he obtained a dark brown residue which on vacuum distillation (to remove excess phenol) changed to a ruby-red, transparent jelly. This jelly crystallized readily yielding dihydroxy-triphenylmethane.

Benzal bromide (25 parts) and Swedish rosin (140 parts) were fused together by Kränzlein and Voss.<sup>63</sup> As the reaction proceeded the mixture became so thick that it could no longer be stirred. To avoid this, chlorobenzene was added and the mass held at 200-210°C. for 2 hours. The volatile constituents were removed at 200°C. by reducing the pressure and the product esterified by refluxing with glycol for 5-6 hours. After distilling the volatile constituents, a resin was obtained which was soluble in drying oils producing varnishes with good resistance to light.

**Benzotrichloride Resins.** Döbner<sup>64</sup> described various condensation reactions of benzotrichloride and noted the tendency to resin formation in many of these. From benzotrichloride and phenol, he obtained both dihydroxytriphenylcarbinol and a yellow resin. Döbner and Schröter<sup>65</sup> added 46 g. of benzotrichloride drop by drop to 50 g. of o-cresol on a water bath. The product, freed from excess cresol by treatment with steam, consisted of a dye and a resin. Treatment with hot sodium bisulphite solution dissolved the dye leaving a yellow resin. Reactions between  $\alpha$ - and  $\beta$ -naphthol<sup>66</sup> and pyrogallol<sup>67</sup> with benzotrichloride are reported as producing resinous substances along with crystallizable bodies.

Heiber<sup>68</sup> treated a solution of sodium phenolate (containing 3 mols of phenol) with 1 mol of benzotrichloride, heating on a water bath until the odor of the chloride had disappeared. After acidifying and washing with water to remove excess phenol, the product yielded on distillation with steam a bright-yellow distillate and a reddish-yellow, resinous residue. The distilled oil was shown by Heiber to contain phenyl benzoate and what was believed to be o-hydroxybenzophenone. The same products were obtained by Hamada.<sup>69</sup>

Ellis<sup>70</sup> prepared a resin by heating 3 mols of phenol with 1 mol of crude benzotrichloride (chlorinated toluene) in alcoholic solution (at its boiling point) in the presence of ferric or aluminum chloride. The mass became insoluble and infusible within an hour, if aluminum chloride was used as the catalyst. If no condensing agent was added, the reaction occurred in two stages, first with the formation of a syrupy liquid (within 40 minutes) which on further heating lost water and became dark brown and semi-solid. Ultimately a solid resin resulted. When the syrupy product was heated with formaldehyde solution (40 per cent), it was converted into a tough, red, rubbery mass which hardened on further heating.<sup>71</sup> The addition of 10 per cent hexamethylenetetramine greatly accelerated hardening.<sup>72</sup> Prior to treatment with formaldehyde, excess phenol may be removed by steam distillation.<sup>73</sup>

A hard resin is produced by the condensation of benzotrichloride with aniline. This reaction occurs in two stages, yielding first a dark green, heavy oil and finally a dark red resin. Paraformaldehyde or hexamethylenetetramine accelerates hardening of the resin. Condensation of benzotrichloride with benzene (2 mols) in the presence of anhydrous aluminum chloride yields a resin easily soluble in benzene, together with a small amount of triphenylcarbinol and benzoic ester.<sup>74</sup>

Wohl and Wertyporoch<sup>75</sup> studied the action of aluminum chloride on benzotrichloride. Five per cent of aluminum chloride was added and after the mixture had been heated for 4 hours at 50-60°C., it yielded m-trichloromethyl-diphenyldichloromethane, m-(m-trichloromethyl-dichlorobenzyl)diphenyldichloromethane and a highly polymerized, insoluble resin containing chlorine. Either of the diphenyldichloromethane derivatives could be converted into higher condensates and resins by heating further with aluminum chloride. Such compounds are therefore to be regarded as resin intermediates. This would indicate that the course of

resinification of benzotrichloride in the presence of aluminum chloride involves initial formation of chains which may be represented:

Probably only one<sup>76</sup> of the chlorine-atoms of each  $\text{CCl}_2$ -group is involved in this condensation; and, since combination may occur at any free meta position, the final insoluble polymer would correspond to a structure consisting of groupings that may be represented:

Tars are formed by the action of cadmium and lead oxides on benzotrichloride.<sup>77</sup>

**Resins from Naphthalene Chlorides.** The chlorine addition products of naphthalene<sup>78</sup> behave in a manner analogous to the other aralkyl chlorides. When heated with aluminum chloride, naphthalene tetrachloride is resinified and the resin so obtained is soluble in benzene, turpentine and linseed oil, but insoluble in alcohol. Its use in the manufacture of varnishes and lacquers has been recommended. Another procedure consists in dissolving 100 parts of naphthalene tetrachloride in 400 parts of toluene, adding 3.5 parts of aluminum chloride and heating for several hours on a water bath. The solvent is expelled by distilling with steam and the resin freed from moisture by further heating to  $150^\circ\text{C}$ . A clear, brittle resin is obtained. A similar product is formed by heating a mixture of 300 parts of xylene, 100 parts of naphthalene tetrachloride and 3 parts of ferric chloride, first on a water bath and then for several hours at  $130^\circ\text{C}$ . The crude chlorinated material, a mixture of naphthalene di- and tetrachlorides prepared by chlorinating 256 parts of naphthalene in 800 parts of chloroform until about 3.5 atoms of chlorine have been added, may be converted to resin by several hours heating with 20 parts of aluminum chloride. Antimony pentachloride also acts as a condensing agent. A hard resin is made from the dichloro derivative of tetrahydronaphthalene by adding 5 per cent of aluminum chloride and heating to  $200^\circ\text{C}$ . By dissolving 30 parts of the dichloro derivative in 120 parts of toluene, adding 1 part of aluminum chloride and boiling the mixture under reflux for several hours a semi-solid resin is obtained whose solution in benzene dries to a varnish-like coating. More highly chlorinated derivatives of tetrahydronaphthalene yield brittle resins when heated to  $250^\circ\text{C}$ . in the presence of 0.7 per cent of ferric chloride. The bromine derivatives yield similar resins.<sup>79</sup>

Naphthalene chlorides heated (without solvents) with a small amount of a metal or metallic compound yield hard resins, e.g., naphthalene tetrachloride heated to  $215^\circ\text{C}$ . with 0.5 per cent of ferric oxide.<sup>80</sup> This resin when dissolved in acetone

<sup>76</sup> O. Döbner (*Ann.*, 1833, 217, 226; *J.C.S.*, 1833, 44, 361) noted that one of the chlorine atoms of benzotrichloride cannot be displaced by aromatic groups.

<sup>77</sup> W. Davies and J. H. Dick, *J.C.S.*, 1932, 2808.

<sup>78</sup> Naphthalene chlorides such as naphthalene tetrachloride,  $\text{C}_{10}\text{H}_6\text{Cl}_4$ , should not be confused with the chlorine substitution products of naphthalene such as tetrachloronaphthalene,  $\text{C}_{10}\text{H}_4\text{Cl}_4$ . The latter are analogous to chlorobenzene and are less prone to form resins by the above processes. Naphthalene chlorides are formed either by the chlorination of naphthalene in the dark and in the presence of a halogen-carrier or by the chlorination of tetrahydronaphthalene.

<sup>79</sup> German P. 332,391, 1918, to A.-G. für Anilin-Fabrik; *J.S.C.I.*, 1921, 40, 353A.

<sup>80</sup> E. Freund and H. Jordan, *German P.* 466,282, 1928, to Schering-Kahlbaum A.-G.; *Chem. Abs.*, 1929, 23, 1000.

or carbon tetrachloride may be used as a lacquer.<sup>61</sup> Florenz added chlorine to anthracene and phenanthrene suspended in carbon disulphide or benzene and, after evaporating the solvent, treated the residues with condensing agents to form resins.<sup>62</sup> Anthracene dibromide with sodium acetate gives resinous products.<sup>63</sup>

Hydrosilicates of aluminum and magnesium, such as fuller's earth, franconite or tonsil, are capable of functioning as catalysts in the Friedel-Crafts reaction. When a mixture of equimolecular quantities of naphthalene and naphthalene tetrachloride is slowly heated with 0.1 per cent of fuller's earth to about 60°C., a vigorous evolution of hydrogen chloride takes place. After heating at 120°C. for 2 hours, the portion soluble in carbon tetrachloride is a dark green, brittle resin which softens at 65°C. Substitution of phenols (from low-temperature coal tar) for naphthalene gives a green mass which softens at 85°C. and is soluble in alcohol.<sup>64</sup> 1,2-Dibromo-ac-tetrahydronaphthalene, chlorinated decahydronaphthalene and pinene hydrochloride also give resins when heated with fuller's earth; and, under the same conditions, a solution of benzyl chloride in xylene forms a saturated viscous oil.<sup>65</sup>

In the presence of condensation agents, naphthalene chlorides react with formaldehyde to form hard resins.<sup>66</sup>

Resins soluble in benzene, chloroform, linseed oil, turpentine and alcohol are made by heating phenols with naphthalene chlorides in the presence of metal halides, with or without the addition of solvents. Typical examples are: Phenol heated to 90-95°C. with a solution of naphthalene tetrachloride in tetrachloroethane, and ferric chloride; o-cresol heated to 100°C. with a solution of naphthalene tetrachloride in o-dichlorobenzene; and ferric or aluminum chloride; and phenol heated to 100°C. with ferric chloride and the product obtained by chlorinating tetrahydronaphthalene at ordinary temperature until four atoms of chlorine have been added.<sup>67</sup>

**Alkyl and Acyl Halides.** In addition to reactions involving many types of alkyl halides, resins have been formed by the interaction of various alkyl and acyl halides on aromatic compounds. Shinkle<sup>68</sup> condensed aromatic hydrocarbons with ethylene dichloride in the presence of aluminum chloride. The products are reported as being resistant to abrasion, solvents and heat. They may be chlorinated to reduce the flexibility. Resins (from ethylene dichloride and benzene) mixed with rubber and sulphur and vulcanized give a material recommended for the manufacture of hoses which must be resistant to gasoline.<sup>69</sup> Or the resins, after alkylation which renders them soluble in petroleum hydrocarbons, may be used as thickening agents for hydrocarbon oils.<sup>70</sup>

A dark green, viscous oil is formed by boiling 40 parts of acetylene tetrabromide with 20 parts of xylene and 1 part of fuller's earth until evolution of

hydrogen bromide ceases.<sup>91</sup> Reaction between phenol and acetylene tetrabromide in aqueous alkali has been studied in the author's laboratory. Several products were obtained, one of which was a fusible resin. It could be hardened by boiling with formaldehyde in the presence of alkali and then adding hexamethylenetetramine.

The resinous by-products from the preparation of salicylaldehyde were also studied.<sup>92</sup> The yield of resin could be raised to 62 per cent by heating the mixture after the addition of the chloroform to the sodium phenolate solution for 3 hours instead of 30 minutes. This resin also could be hardened by the addition of 2 per cent of hexamethylenetetramine. Phenol and trichloroethylene likewise gave an oily substance which was hardened by boiling with formaldehyde solution and adding hexamethylenetetramine and could be used as a molding composition.

Mixtures of ethylene and propylene chlorohydrin were condensed with aniline and phenol. In the latter case both aluminum chloride and sulphuric acid were used as condensing agents. In the case of the aniline, boiling of the reactants in the presence of water was sufficient. The product, after treatment with paraldehyde and then hexamethylenetetramine, could be molded. It was a brittle, lustrous resin.

Reaction of aniline with carbon tetrachloride in the presence of a copper catalyst yielded a resin.<sup>93</sup> Similarly sodium anilide and trichloroethylene gave a red-black, tarry substance which was believed to consist of condensation products of aniline and monochloroacetylene.<sup>94</sup> Dichloroethylene also furnished a plastic mass when it was treated with formaldehyde under the catalytic influence of sulphuric acid.<sup>95</sup>  $\beta$ -Chloroethylaniline is said to be an unstable compound which polymerizes to a chlorine-free solid of unknown constitution.<sup>96</sup>

Kleinfeller and Frercks<sup>97</sup> attempted to bring about cyclizations leading to substances having an arrangement of carbon atoms similar to the diamond space lattice. They interacted 2-chloromethyl-1,3-dichloro-2-nitropropane and phloroglucinol in methyl alcohol in the presence of sodium methoxide. The products obtained were a reddish-brown resin and 1,3-diethoxy-3-chloromethylenepropane,

As the result of the reaction of cinnamyl chloride in nitrobenzene with phloroglucinol and aluminum chloride, Rosenmund and Rosenmund<sup>98</sup> obtained much resinous matter, a compound,  $\text{C}_{16}\text{H}_{12}\text{O}_4$ , and a substance melting at  $210^\circ\text{C}$ . Hexahydrodiphenylene oxide readily becomes resinified under the conditions of the Friedel-Crafts reaction, but with careful control it can be combined with acetyl chloride to give the corresponding methyl ketone.<sup>99</sup> Wieland and Hasegawa<sup>100</sup> described the reactions of acetyl and benzoyl chlorides with 1,4-diphenyl-1,3-butadiene in benzene in the presence of aluminum chloride. The crystallized prod-

ucts possessed quite high molecular weights pointing to complex condensations and polymerizations. The acetylchloride derivative possessed the formula,  $C_{20}H_{28}O_2Cl$ ; the benzoyl,  $C_{20}H_{20}O$ . Acetyl chloride and camphene in ether with aluminum chloride as a catalyst gave a large amount of resin. Jackson and Kenner added aluminum chloride to  $\beta$ -phenylglutaryl chloride in purified light petroleum and obtained a tar and 1-ketohydrindene-3-acetic acid. When benzene was present in the solution  $\omega$ -3-hydrindonylaceto-phenone was also formed. This is similar to the action of hydrocarbons in stopping the condensation of benzyl chloride.<sup>101</sup>

Pyridine will dissolve copper halides and so has been described as a catalyst in the condensations of organic halogen compounds in the presence of copper. Reactions involving the use of this combination are often accompanied by resin formation.<sup>102</sup>

Shellac substitutes have been produced by the condensation of fatty acids with "resinol"<sup>103</sup> or hydroaromatic acids. Combination can be accomplished in several ways. Chlorinated derivatives of the unsaturated fatty acids may be heated with the resinolic acid, or the chlorine derivatives of either fatty acids or resinolic acids may be condensed with the hydroxy derivatives of the other.<sup>104</sup> For example, trihydroxystearic acid was heated in the presence of aluminum chloride with chlorinated abietic acid. The latter was formed by passing chlorine into an alkaline solution of rosin and then precipitating with a mineral acid. Or the acids of linseed oil were chlorinated in benzene and heated with a solution of hydroxycyclohexanecarboxylic acid in benzene. Another modification was to chlorinate both reactants.<sup>105</sup>

<sup>105</sup> J. Scheiber, U. S. P. 1,927,472, Sept. 19, 1933; *Chem. Abs.*, 1933, 27, 5993.

Prins<sup>106</sup> investigated the reactions of chlorinated paraffins with chloro-olefins. Chloroform condensed with tetrachloroethylene in the presence of aluminum chloride to give heptachloropropane. The reaction went most rapidly with monochloroethylene. Sometimes higher condensation products were isolated due to the loss of hydrogen chloride and formation of reactive chloropropenes or, more generally, of an unsaturated compound with a vicinal trichloromethyl or dichloromethylene group.

Resinous compounds which can be added to lubricating oils to improve their viscosity, color and pour points, are made by combining chlorinated wax (containing 20 per cent chlorine) with naphthalene, using aluminum chloride as a catalyst.<sup>107</sup> Only a small proportion, 0.2-1.0 per cent, of the resin need be incorporated with the oil. An alternative procedure consists in fractionally precipitating (by cooling) the chlorinated wax from a solvent, and treating the individual fractions with naphthalene.<sup>108</sup> Or the separate fractions may be polymerized by the action of aluminum chloride and the polymers used as described above.

**Miscellaneous Condensations.** Angeletti in attempting to prepare the 2-halo-2'-nitro-6,6'-bitolyls by the Sandmeyer reaction on dl-2-amino-2'-nitro-6,6'-bitolyl obtained tars and resins as by-products.<sup>109</sup> Koller<sup>110</sup> tried to obtain 1,8-naphthyridine by reducing 2,4-dichloronaphthyridine. With hydrogen and palladium a mixture of chlorinated and hydrogenated derivatives of naphthyridine resulted. This could not be distilled since it resinified on heating. Resinification interfered with the preparation of cyanoanthrones from chloroanthrones.<sup>111</sup> In the presence of condensing agents chlorinated naphthalenes which contain one hydrogen atom may be combined with glycolic acid, glycolide or oxalic acid.<sup>112</sup> Tribromophenol bromide loses bromine very readily to form amorphous products.<sup>113</sup> Oxidation of trichlorophenol produced polynuclear quinones and also an amorphous oxide.<sup>114</sup> Refluxing a toluene solution of 9-bromofluorene and mercury di-p-tolyl gave a tarry mass from which bis-diphenylene ethylene was isolated.<sup>115</sup>

The residue obtained by distilling together ethyl 1,4-dibromobutane-1,1,4,4-tetracarboxylate and phenol yielded, on boiling with hydrochloric acid, adipic acid and a dark gum.<sup>116</sup>

Schaarschmidt and Raack<sup>117</sup> attempted to prepare nitrosobenzene by the action of nitrosyl chloride on benzene in the presence of aluminum chloride. The principal purified compound from 65 g. of nitrosyl chloride, 240 g. of benzene and 270 g. of aluminum chloride was 55 g. of p-aminobiphenyl which was accompanied by 120 g. of an indefinite, brown product. Benzene and aluminum bromide on long standing produce a resin.<sup>118</sup>

Shoesmith<sup>119</sup> has stated that the hydroxybenzyl alcohols resulting from the hydrolysis of  $\omega$ -chlorotolyl carbonates show a very strong tendency to resinify in the presence of acids. Diphenyl- $\alpha$ -naphthylchloromethane in benzene, when kept in contact with mercuric oxide for several days, gives a 50 per cent yield of diphenyl- $\alpha$ -naphthyl carbinol. The remainder is precipitated as a gum by petroleum ether.<sup>120</sup>

Bigot<sup>121</sup> found among the reaction products of 3-chloro-1,2-epoxypropane (dissolved in ether) and sodium, an insoluble rubber-like material. The preparation of di-p-chlorobenzoyl propane from glutaryl chloride and chlorobenzol is accompanied by resinification.<sup>122</sup>

The treatment of diphenylaminocyclobutane carboxylic acid in ether solution with nitrosyl bromide gives a lactone. A resin is left in solution in the mother liquor.<sup>123</sup>

**Resins by the Würtz-Fittig Reaction.** In the reaction of chlorobenzene with sodium only a small amount of resinous material is obtained,<sup>124</sup> but when more highly substituted compounds, such as p-dibromobenzene,<sup>125</sup> are used, the products are resinous. If the reaction of p-dibromobenzene and sodium is conducted in ether, a polymer with a composition corresponding to  $C_{16}H_{12}Br_2$  is formed after three days. Higher polymers are formed after a longer time.<sup>126</sup> Jacobson<sup>127</sup> considers the molecular structure of these polymers to be p-phenylene chains with bromine atoms at each end:

The polymers are soluble but infusible. In liquid ammonia a tar is obtained from o-dichlorobenzene and sodium.<sup>128</sup> p-Xylylene dibromide<sup>129</sup> reacts with sodium in toluene to give an insoluble, infusible polymer of the empirical formula,  $(C_8H_6)_n$ , isomeric with polystyrene.<sup>130</sup> The constitution of the material may be represented as a long chain of xylylene-groups,  $(-CH_2-C_6H_4-CH_2-)_n$ .

In the preparation of Grignard reagents from dihalogenated benzene, tars are produced.<sup>131</sup> With p-dibromobenzene some p-dibromobiphenyl was isolated. Acetyl bromide and magnesium in ether give diacetyl and a resin. The product of the

decomposition with water also contains ethyl acetate.<sup>132</sup> The substance from the reaction of magnesium with 1,4-dibromonaphthalene is converted by water into naphthalene, 1-bromonaphthalene and resinous matter.<sup>133</sup> 1,2-Dibromonaphthalene and magnesium also give tarry matter. Triphenylmagnesium bromide yields tars or oils when treated with oxygen, thionyl chloride and triphenylchloromethane.<sup>134</sup>

2,2'-Diiodobiphenyl and o-iodobromobenzene when heated with copper gave resinous products.<sup>135</sup>

## CLASS II. RESINS BY HALOGENATION

In this class of compounds which owe, as has been said before, their resinous properties to the fact that they are complex mixtures of individuals, the principal members are the chlorinated biaryls and naphthalenes. The first of these have come into use due to the commercial preparation of biphenyl. However their applications, principally as insulators for condensers and transformers, thus far are very limited. The older method of synthesizing biphenyl, which was discovered by Berthelot, consisted of passing benzene through a hot tube.<sup>136</sup> This process has since been modified in that benzene vapor, preheated to 650°C., is brought in contact with liquids such as molten lead or metal salts at about 800°C. A certain per cent of higher homologues is also formed and, if desired, this percentage may be increased by raising the temperature.<sup>137</sup>

Williams<sup>138</sup> made polyphenyls, which are oily or waxy materials, by heating (to 650-950°C.) a mixture of benzene and biphenyl with 0.1 per cent or more of sulphur, hydrogen sulphide, carbon disulphide or sulphur dioxide.

**Preparation of Halogenated Biaryls.** The early investigators chlorinated biphenyl in the presence of various catalysts. Kramers<sup>139</sup> used antimony chloride and an amount of chlorine equivalent to the monochloro derivative. The products that he isolated were 2- and 4-chlorobiphenyl, 4,4'-dichlorobiphenyl and a high-boiling residue. Schmidt and Schultz<sup>140</sup> used iodine as a catalyst and obtained 4,4'-dichlorobiphenyl. Weber and Sölscher<sup>141</sup> found that at high temperatures chlorination gave tarry products which interfered with the crystallization of the less highly chlorinated compounds. Merz and Weith<sup>142</sup> noted that a bright brown, resinous mass was formed when crude chlorobiphenyl was heated.

Later, Jenkins<sup>143</sup> observed that iron was a good catalyst for the chlorination of biphenyl and that by controlling temperature, time and rate of flow of chlorine it is possible to vary and greatly increase the degree of chlorination. In his process an iron vessel is employed, around which is wound a coil for regulation of the temperature. The vessel is filled with iron packing material and molten biphenyl poured in until the catalyst is just covered. Chlorine is forced up

through the biphenyl and at the top of the container an outlet is provided for the escape of hydrogen chloride. Since chlorination proceeds with considerable evolution of heat, cooling water is circulated at the start through the coil to keep the temperature at about 80°C. If the monochloro product is desired, the temperature is gradually decreased to 66°C. and chlorination stopped when the weight of the reaction mixture has increased by an amount equal to 80-95 per cent of that required for complete monochlorination. The product, washed with water to remove chlorides of iron and distilled, yields 50-80 per cent monochlorobiphenyl. To make higher-chlorinated products, the temperature is allowed to rise to 175-220°C. during the progress of the reaction. At these temperatures, according to Jenkins, it is possible to chlorinate smoothly and rapidly to a mixture of chlorobiphenyls with an average chlorine content of 70 per cent. The degree of chlorination can be found by determining the specific gravity of samples of the product;

FIG. 148.—Specific Gravity as a Function of Chlorine Content in Chlorinated Biphenyl. (R. L. Jenkins.)

Figure 148 shows the relation between the specific gravity and chlorine content as determined by Jenkins.

Another process involves chlorination at a temperature slightly above the melting point. Antimony chloride is used as a catalyst.<sup>144</sup> In the presence of carriers, Britton and Stoesser<sup>145</sup> chlorinated biphenyl in various solvents at -10 to 40°C. Among the solvents used were benzene and its liquid halogenated derivatives. 2-Chloro-, 4-chloro-, 4,4'-dichlorobiphenyl and other isomeric dichloro- compounds were formed. The use of iron as a catalyst and highly chlorinated biphenyl as the solvent has been proposed.<sup>146</sup>

When the chlorine content of the product from chlorination of technical biphenyl reaches about 68 per cent, the material (which up to this point has remained a viscous liquid) suddenly becomes crystalline. The softening points of the chlorinated biphenyl mixtures which contain less than 68 per cent chlorine are rather low, usually below 64°C. In order to keep the higher-chlorinated biphenyls in a permanently stable, non-crystalline, solid state and to raise the softening point of the chlorinated biphenyl mixture, various percentages of the high-boiling compounds which are formed in the thermal synthesis of biphenyl are added to the crude biphenyl. In the accompanying graph (Fig. 149) there is shown the effect, according to Jenkins,<sup>147</sup> of different proportions of the high-boiling constituents on

<sup>144</sup> British P. 360,840, 1930, to I. G. Farbenind. A.-G.; *Chem. Abs.*, 1933, 27, 1014. French P. 716,261, 1931; *Chem. Abs.*, 1932, 26, 2200.

<sup>147</sup> R. L. Jenkins, U. S. P. 1,892,393, Dec. 27, 1932, to Swann Research, Inc.; *Chem. Abs.*, 1933, 27, 2032. British P. 358,704, 1930, to Federal Phosphorus Co.; *Chem. Abs.*, 1932, 26, 6165. French P.

the softening point and the crystallizing tendency. The curve *C* which refers to pure biphenyl could not be carried to higher softening points because of tendency to crystallize. By chlorinating the high-boiling compounds alone, still higher softening points may be obtained. One sample of such a mixture, reported by Jenkins, had 63.9 per cent chlorine and a softening point of 125.5°C.

In order to increase the proportion of complex, high-boiling constituents formed in the thermal synthesis of biphenyl, Durgin and Jenkins<sup>140</sup> increased the tempera-

FIG. 149.—Softening Point as a Function of the Chlorination of (A) 60 per cent Biphenyl and 40 per cent High-Boiling Polyphenyls, (B) 80 per cent Biphenyl and 20 per cent High-Boiling Compounds and (C) 100 per cent Biphenyl. (R. L. Jenkins.)

ture of the bath of molten liquid and also used crude benzene. They state that when the reaction temperature is 750°C., the percentage of crude biphenyl, or the fraction boiling between 200° and 270°C., is approximately 4.5 per cent of the total condensate and that boiling about 270°C. is 0.4 per cent. By increasing the temperature to 850°C. the crude biphenyl fraction rises to approximately 15.5 per cent and the high-boiling to 5 per cent. If 90 per cent benzene is used in place of pure benzene and the temperature held at 850°C., the product, other than benzene, contains 30.5 per cent of the compounds boiling at 270°C.

In the presence of iron or nickel, the product of chlorination is colored. To obtain a clear, transparent product, Jenkins and Sikarski suggested iodine as a catalyst. For example, 60 g. of biphenyl and 40 g. of the high-boiling biaryl mixture were chlorinated. At the start 0.04 g. of iodine was added; and, as this was volatilized, additional 0.04 g. lots were added until a total of 0.4 g. was reached.

702,593, 1930; *Chem. Abs.*, 1931, 25, 4422. W. A. Cook and K. H. Cook (*J.A.C.S.*, 1933, 55, 1212) have studied the halogenation of *m*-diphenylbenzene.

<sup>140</sup> C. B. Durgin and R. L. Jenkins, U. S. P. 1,894,266, Jan. 17, 1933, to Swann Research, Inc.; *Chem. Abs.*, 1933, 27, 2459. For a description of these high-boiling substances, see W. A. Cook and K. H. Cook, *J.A.C.S.*, 1933, 55, 1212.

The temperature was held at 70°C. at the beginning of the reaction, but towards the end it was raised to 175-200°C.<sup>149</sup>

The same investigators distilled the initial products of chlorination and separated compounds having a wide range of softening points and varying from white to light yellow in color.<sup>150</sup> For example, molten, technical biphenyl was chlorinated until it had a specific gravity of 1.65 at 65°C. The product at this stage was a black solid having a chlorine content of approximately 63 per cent and an A.S.T.M. softening point of 50°C. This on distillation gave a soft, sticky wax having a Saybolt viscosity of 127 seconds at 210°F. When a mixture of biphenyl and 40 per cent of the higher biaryls was used, similar products were obtained. The softening points of the distillates in this case are shown in Figure 150.

FIG. 150.—Softening Points of Chlorinated Biaryl Distillates. (R. L. Jenkins and J. A. Sikarski.)

**Properties and Uses of Chlorinated Biphenyl Resins.** These compounds have been produced commercially under the trade name "Aroclors."<sup>151</sup> The Aroclors range from a water-white, mobile oil to an amber-colored, transparent resin softening at 70°C. (see Fig. 151). The latter product is not combustible. Table 59 (on page 1146), which is abbreviated from one given by Penning,<sup>152</sup> gives the physical properties of some chlorinated biphenyl resins.

The Aroclors are soluble in a wide range of solvents. The principal ones in which they are insoluble or difficultly soluble are those which contain water or more than one hydroxyl group in the molecule, as for example, 95 per cent alcohol or glycerol.<sup>153</sup>

Aroclors are not hydrolyzed under ordinary conditions. Furthermore, they

may be boiled with 10 per cent sodium hydroxide solution with no change. They are thermoplastic and nondrying, i.e., do not polymerize or oxidize on standing. They may be heated indefinitely at 150°C. and for short periods at higher temperatures with no apparent change. The light oils can be distilled at atmospheric pressure, and under vacuum the viscous oils and the solids can also be distilled. They have low vaporization losses. For the solids at 66°C., it is less than 0.04 g. per square inch per month.

FIG. 151.—Various Grades of Aroclors.

**Chlorinated Biphenyls in Varnishes and Dressings.** The viscous Aroclors are soluble in linseed and tung oils and may be employed as resins or gums in varnishes, particularly those of the short oil type in which cracking is due to the presence of brittle resins.<sup>134</sup> Varnishes made from the Aroclors are reported to be resistant to water and alkalis and partially so to flames. Gardner<sup>135</sup> prepared quick-drying varnishes and lacquers using chlorinated biphenyls mixed with other resins and oils. For example, 25 parts of chlorinated biphenyl were added at a temperature not above 190°C. to 132 parts of glycerol phthalate. Then 100 parts of this mixture were boiled with 200 parts of tung oil until a homogeneous composition was formed. This was thinned with turpentine before use. Gardner found that in this way he could produce a tough, light-colored film.

Although the lower chlorination products of biphenyl will burn, the higher derivatives do not and so may be used for flame-proofing purposes. According

<sup>134</sup> C. H. Penning, *loc. cit.* R. L. Jenkins, U. S. P. 1,974,801, Sept. 25, 1934, to Swann Research, Inc.; *Chem. Abs.*, 1934, 28, 7562. L. D. Gittings (U. S. P. 1,974,799, Sept. 25, 1934, to Swann Research, Inc.; *Chem. Abs.*, 1934, 28, 7553) has proposed a chlorinated biphenyl having approximately the formula  $C_{12}H_7Cl_5$  as a pigment with tung oil for a varnish.

<sup>135</sup> H. A. Gardner, U. S. P. 1,937,678, Nov. 15, 1932; *Chem. Abs.*, 1933, 27, 1530. British P. 351,637, 1930; *Chem. Abs.*, 1932, 26, 3125. German P. 563,080, 1930; *Chem. Abs.*, 1933, 27, 1539.

to Penning,<sup>126</sup> a practically fireproof material can be obtained by impregnation of wood with certain of the Aroclors, but the cost is considerably greater than when mineral salts are used. It is stated that the treated wood, however, instead of being brittle and lifeless, as is the case with the mineral-salts process, gains in strength. Impregnation of wood, fabric and paper with polychlorinated naphthalenes or biphenyls has been investigated by Engelhardt.<sup>127</sup> The latter substances mixed with ceresin and aluminum stearate are proposed also as agents to render textiles waterproof and fire-resistant.<sup>128</sup>

Darrin<sup>129</sup> used chlorine-substituted products of biphenyl as introfiers for the introduction of sulphur into the pores of paper, wood and ceramics. For example, 35 parts of sulphur were fused with 65 parts of resinous chlorobiphenyls. Paper material could be impregnated by dipping into the molten material, or if only a surface coating was desired, the mixtures could be sprayed or brushed on. The result was a hard, resistant, impervious, fireproof substance. Addition of selenium to the sulphur-chlorinated-biphenyl mixture increased protection against fire. For example, a composition of 40 parts of chlorinated biphenyls, 100 parts of sulphur and 15 parts of selenium exhibited as good a fireproofing quality and was much harder than one of 100 parts of sulphur and 200 parts of chlorinated biphenyls.<sup>130</sup>

Powdered sulphur coated with a fireproofing agent is prepared by spraying a mixture of molten sulphur and chlorinated biphenyl into a cooled atmosphere.<sup>131</sup> Sulphur so treated may be employed for impregnation of wood, porous pulp or paper. Gardner<sup>132</sup> employed a product obtained from heating sulphur with chlorinated biphenyl to assist the solution of heat-convertible phenol resins in drying oils.

Metal articles may be protected by coating with a layer of asphalt, then a layer of asbestos paper or felt saturated with a mixture of asphalt and chlorinated polyphenyl, and finally with a layer of asphalt.<sup>133</sup> Koch<sup>134</sup> used a solution of chlorinated rubber and chlorinated biphenyl in xylene or toluene to coat pipes which were to be buried underground.

Charch<sup>135</sup> employed as a moisture-proof, nontacky, flexible coating for sheets of regenerated cellulose, a composition made up of 1 part of chlorinated biphenyl, 0.33 part of a high-melting paraffin wax and 0.5 part of a plasticizer. Another suggested mixture consists of chlorinated polyphenyl (62.5 parts), dibutyl phthalate (5.4 parts) and finely ground silica (32.1 parts).<sup>136</sup>

According to Jenkins and Foster,<sup>137</sup> the Aroclors, although possessing both softening and resinous properties, are not to be regarded as exact substitutes for any of the present constituents of lacquers. In descending the series from the more viscous Aroclors to the less viscous, compatibility with nitrocellulose increases, as well as solubility in solvents. On the other hand with increase in viscosity,

Aroclors have increased resistance to discoloration by sunlight; higher softening-, flash- and fire-points; less odor and volatility but a greater tendency to crystallize. For a lacquer, the choice of Aroclor depends on a balance of the above properties.

Jenkins and Foster made solutions of equal concentrations of Aroclors and 0.5-second nitrocellulose, mixing them in proportions to give a series of lacquers

(R. L. Jenkins and R. N. Foster.)

and down, give blushed films or ones that sweat. With the third components used in the systems plotted in Figure 153, there is an ample range of compatibility for the preparation of most types of varnishes. Those of Figure 154, on the other hand, require the addition of plasticizers.

The effect of different types of solvents on the compatible area is indicated by the curves. Keys to the resins and solvents studied are given in Tables 61 and 62 respectively.

TABLE 62.—*Solvents Used in Studying Compatibility.*

Solvent	Composition
1	Technical amyl acetate.
2	50 parts toluene, 6.4 parts alcohol (specially denatured, formula 3-A), 6.4 parts butyl alcohol, 6.4 parts ethyl acetate, 30.8 parts butyl acetate.
3	70 parts toluene, 10 parts alcohol (specially denatured, formula 3-A), 10 parts ethyl acetate, 10 parts cellosolve.
4	65 parts toluene, 10 parts butyl alcohol, 25 parts butyl acetate.

Blom<sup>167</sup> has made a study of the effect of Aroclors on the mechanical properties of nitrocellulose films. It was found that the films showed increased breaking load and good elasticity and did not become brittle with additions up to 75 per cent of nitrocellulose. Castor oil was found to be an unsatisfactory plasticizer for nitrocellulose-Aroclor films because it tended to cause sweating.

The resinous Aroclors adhere strongly to glass and metal and it is said that joints between metal and glass surfaces are stronger than similar joints made with glue. However, the thermoplasticity of the resins is a disadvantage in this field. Gardner<sup>168</sup> reports that in making a shatterproof glass good adhesion is obtained when a chlorinated biphenyl resin is used in conjunction with a sheet of regenerated cellulose between the two glass plates. A cement consisting of resinous chlorobiphenyls and oxidized or polymerized oils has been used in the making of linoleum.<sup>169</sup> Jenkins prepared an odorless adhesive by chlorinating a mixture of polyphenyls.<sup>170</sup> Hetherington and Sim<sup>171</sup> also have made floor coverings from benzylcellulose, aromatic ethers of a polyhydric alcohol, fillers and chlorinated biphenyl or chlorinated naphthalene. It should be noted that chlorinated biphenyl has also been used as a plasticizer for benzylcellulose in lacquers.<sup>172</sup>

**Use of Molding and Insulating Compounds.** The thermoplastic properties of the Aroclors prevent their having more than restricted use as molding compounds. However, where it is desired to remelt and recast the compound, Aroclors have an advantage over natural waxes that on heating they are not altered in character through the loss of easily volatile constituents. Jenkins and Hardy<sup>173</sup> made a sealing wax from pine rosin and a biphenyl resin. For example, 100 parts of a black chlorinated biphenyl resin having a softening point of 72°C. were mixed with 100 parts of pine rosin and heated at 160°C. until a fluid product resulted. Two hundred parts of fine, red iron oxide were then stirred in. The melt was cast into molds.

The electrical properties of Aroclors are said to be very good, having a high dielectric constant and resistivity and a low power factor.<sup>174</sup> In fact, one of the principal outlets for the Aroclors has been in the electrical field. Thus, a dielectric material has been produced by Clark<sup>175</sup> by impregnating paper with halogenated aryl hydrocarbons such as a mixture of trichlorobenzene and hexachlorobiphenyl. Soda lime was included to absorb any hydrochloric acid evolved from the dielectric

due to an arc discharge. Young<sup>176</sup> employed chlorinated biphenyl as an external coating of insulation on metal wire. An insulating composition has been made from chlorinated biphenyl by subjecting it to a high-tension electrical field and then purifying by distillation or filtration over Florida earth.<sup>177</sup> Another procedure is the chlorination of a mixture of biphenyl and other aromatic hydrocarbons (e.g., naphthalene) until the chlorine content reaches a value of 50-55 per cent.<sup>178</sup> A further proposed dielectric consists of a mixture of chlorinated biaryl and chlorinated olefin, e.g., dichlorostyrene.<sup>179</sup>

The use of a fluorinated aliphatic hydrocarbon, e.g., tetrachloro-difluoroethane, in amounts not exceeding 10 per cent of the total weight, with chlorinated biphenyl has been suggested.<sup>180</sup> The composition is improved by distilling in the presence of sodium or iron. The resulting liquid may be used for insulation purposes.

Chlorinated biphenyl may be employed in the manufacture of viscose yarns<sup>181</sup> as a delustering agent, in the preparation of soldering fluxes, particularly for aluminum alloys,<sup>182</sup> and in lithographic printing.<sup>183</sup>

**Chlorinated Naphthalenes.** Chloronaphthalenes in contrast to chlorobiphenyls are not strictly resins.<sup>184</sup> The products obtained from the various degrees of chlorination of naphthalene are wax-like and some of their components may be readily crystallized. According to Ellis,<sup>185</sup> naphthalene is easily chlorinated at 80°C. to about 45-50 per cent chlorine content. The solid material which separates from the naphthalene may be washed with alkali to remove free acid. Antimony chloride, phosphorus chlorides, sulphur and iodine are all catalysts for the reaction.<sup>186</sup> Control of the temperature during chlorination of molten naphthalene has been described by Engelhardt.<sup>187</sup> Payman and Gibson suggested ferric chloride as a catalyst for this reaction,<sup>188</sup> and the use of a solution of naphthalene in carbon tetrachloride at 5°C. with the same catalyst.<sup>189</sup> In both instances the products were distilled under reduced pressure. This method of purification was also used by Brown and Hanson, only they neutralized with lime or sodium hydroxide first.<sup>190</sup> Britton and Reed<sup>191</sup> have prepared chloronaphthalene in aromatic hydrocarbon solvents using iron as a catalyst.

The properties of the chlorinated naphthalenes have been investigated by

Halls<sup>190</sup> who found that these waxes have a density of 1.5-1.7, a melting point range of 65-130°C. and a specific inductive capacity of 4.5-5.5. The compounds were relatively stable, although copper might be tarnished at 120-125°C., if water was present. It was also noted that the melting and boiling points of the chloronaphthalenes increase with the number of chlorine atoms in the molecule.

One of the principal industrial applications of the chloronaphthalene waxes has been in the field of insulating dielectrics.<sup>193</sup> In this connection their high specific inductive capacity is quite an advantage since this permits condensers to be made smaller than they can be when paraffin wax is used. Another advantage is the very slight change in volume in passing from a liquid to a solid. This reduces trouble due to the narrow channels in the dielectric left by solidification of the impregnating agent. There is a fairly linear relation between the capacity of condensers using chloronaphthalenes and the temperature. This facilitates the use and testing of the condensers. These waxes are good flame-proofing substances. It is stated that among the cautions which must be observed when using them are the avoidance of overheating or allowing air to come in contact with the molten mass and the rigid exclusion of water. They also are somewhat volatile and precautions should be taken to dispose of the fumes. Rücker has pointed out that the fumes have injurious effects on the skin. He obtained a refined product by blowing air through the crude chlorinated naphthalene while it is held at 215°C.<sup>194</sup> Others added alkaline substances to prevent irritant action on the skin.<sup>195</sup>

Aylsworth was one of the early investigators of chloronaphthalene insulating materials.<sup>196</sup> He noted that (for the same capacity) smaller condensers were required in which the chloro compounds were the dielectric, the slight effect of temperature on the capacity and the stabilizing action of distillation in the presence of a basic oxide.<sup>197</sup> Among the modifications he introduced was the oxidation of the chloronaphthalene waxes with air and nitric acid to increase the flexibility.<sup>198</sup> Incorporation of the resin from o-cresol and formaldehyde increased the dielectric strength of the chloro waxes.<sup>199</sup> Liquid or solid chloronaphthalenes are said to be useful as assistants in the vulcanization of rubber by sulphur. The resulting hard-rubber compositions were used as insulators or as chemically resistant coatings for metals.<sup>200</sup> Asphalt has been incorporated into these insulators by Edison;<sup>201</sup> while rubber, balata, gutta-percha and other natural and synthetic, oil-soluble resins have been used.<sup>202</sup> Condenser foils have also been manufactured by im-

pregnating sheets with hot castor oil, followed by cooling in molten chlorinated naphthalene.<sup>303</sup>

It has been mentioned above that the chloronaphthalenes are flame-proofing substances.<sup>304</sup> They have been utilized for this purpose by Aylsworth,<sup>305</sup> Ellis<sup>306</sup> and Pyne and Parker.<sup>307</sup> Cloth previously impregnated with an inorganic salt, e.g., ammonium biphosphate, is rendered non-inflammable and waterproof by coating with a mixture of dichloronaphthalenes.<sup>308</sup> Tests on woods impregnated with chlorinated naphthalene indicated that it gave very good protection against insects and in addition stabilized the wood against warping due to changes in humidity.<sup>309</sup>

Engelhardt<sup>310</sup> suggests impregnation of bobbins (to be used in the wet treatment of textile threads) with chlorinated naphthalenes. Daniels<sup>311</sup> treated abrasive wheels (employed in contact with hot water) with a mixture consisting largely of penta-chloronaphthalene and solidifying at about 125°C. The higher chloro derivatives mixed with  $\alpha$ -chloronaphthalene give waterproof polishes.<sup>312</sup>

These products seem to adhere firmly to metallic surfaces and so have been used as coating compositions. The addition of sulphur<sup>313</sup> and other water-insoluble substances as talcum, barium sulphate and chromium sesquioxide<sup>314</sup> produces hard compositions. Delaney<sup>315</sup> mixed solid chloronaphthalene with an ester gum and about 5 per cent of rubber latex to form a cement for glass. Chlorinated naphthalenes have been used also in the preparation of sealing wax,<sup>316</sup> as a binding agent in the manufacture of laminated magnetic cores,<sup>317</sup> as a plasticizer for a silk solution,<sup>318</sup> dissolved in carbon tetrachloride and emulsified with water (using an emulsifying agent, e.g., Turkey-red oil) as an impregnating agent for textiles, an insecticide or a polishing material,<sup>319</sup> and to reduce the luster of rayon.<sup>320</sup>

Chloronaphthalene waxes have been suggested as substitutes for kauri gum and rosin,<sup>321</sup> or when mixed with gilsonite as a filling composition.<sup>322</sup> Chlorinated naphthalene in conjunction with stearic acid and inert materials (e.g., asbestos

or mica) may be molded into acid-proof vessels or floats for hydrometers.<sup>225</sup> Monochloronaphthalene is said to be a carbon remover for internal combustion engines.<sup>224</sup> Tetrachloronaphthalene is suggested for use in soldering as it is decomposed at soldering temperatures yielding hydrogen chloride.<sup>226</sup>

**Miscellaneous Resins by Halogenation.** In addition to the Aroclors and chloronaphthalenes, many other resinous bodies or amorphous compounds have been formed by chlorination of organic substances. In this section a few of these, together with their uses, will be given.

Sym-dichlorourea acts on phenol in alkaline aqueous solutions to form a tar.<sup>227</sup> Cresol, chlorocresol and their homologues, when treated with chlorine at temperatures above 100°C. until nearly free from substances volatile with steam, yield a hard, amorphous mass on cooling.<sup>227</sup> Tanaka, Morikawa and Sakamoto,<sup>228</sup> in attempting to prepare dichlorophenol derivatives for use as antiseptics, found that on passing chlorine into a mixture of 1,3,4-xylenol in carbon tetrachloride on ice, 2,6-dichloro-1,3,4-xylenol is obtained, but if the xylenol is chlorinated in the presence of phosphorus pentachloride at high temperatures a resinous substance is produced.

Tishchenko<sup>229</sup> studied the bromination of various phenols. The brominating agent employed was a solution of bromine in aqueous sodium carbonate. Quinol and pyrogallol were almost wholly resinified. Analogous experiments on  $\beta$ -naphthol using chlorine in place of bromine also gave a tar. Bromination of 1,1'-di- $\beta$ -naphthol is accompanied by the formation of resins.<sup>230</sup> Bromine water reacts with eugenol and isoeugenol to yield tarry materials.<sup>231</sup> The dimer of isoeugenol also is converted into a resin when chlorinated.<sup>232</sup> Meyer and Funke<sup>233</sup> reported that amorphous bodies resulted on treating o-cresolbenzoin with chlorine or iodine. The chlorination of o-benzyl alcohol disulphide led to the formation of a resin.<sup>234</sup>

Other compounds suggested as dielectrics or lubricants are the halogenated, phenyl derivatives of methane or ethane, e.g., chlorinated triphenylmethane and the chlorine derivatives of benzophenone.<sup>235</sup>

Paraffin, ceresin, montan wax, tung oil and petroleum can be chlorinated to a high degree by dissolving in carbon tetrachloride and introducing chlorine for a protracted period. The temperature may rise during the early stages of the reaction. After the temperature begins to fall the chlorination should be continued for some time. A transparent solid body is obtained from paraffin when the chlorine content reaches 70 per cent. Highly chlorinated paraffin is very resistant to acids and alkalies; it is not attacked by boiling 65 per cent nitric acid, concentrated hydrochloric acid or a 10 per cent aqueous solution of caustic soda. In spite of this resistance to strong reagents, there exists the tendency of chlorinated products of this character to split off hydrochloric acid on long standing. Chlorine is not so firmly united as it is in chloronaphthalene.<sup>236</sup>

Schaarschmidt<sup>287</sup> chlorinated molten paraffin above 150°C. until the chlorine content exceeded 61.4 per cent. At 150-160°C. a yellowish, transparent mass was obtained which if heated at 180-200°C. produced a brown, hard substance of high melting point. Free chlorine and hydrogen chloride were removed by passing air through the mass.

Geller<sup>288</sup> has investigated the use of chlorinated paraffin as a constituent of a synthetic chewing-gum base. In one experiment he mixed chloroparaffin resin with depolymerized crepe rubber. When heated, cooled and reheated, the rubber dissolved in the resin mixture which was then cooled and kneaded until a homogeneous mass was formed. Two and one-half parts of "hard" chloroparaffin resin, 1 part of "soft" chloroparaffin resin, 1 part of depolymerized rubber gave a "tough" base; 7 parts of hard paraffin resin, 7 parts of soft and 4 parts of depolymerized crepe rubber yielded a soft base. The hard chloroparaffin resin was made by treatment of paraffin (in carbon tetrachloride) with chlorine until it had about the physical characteristics of pine rosin. If chlorination is stopped when the fluid becomes thick then the soft form is obtained. Additional substances which Geller employed were stearin and calcium or magnesium stearate.

Groggins<sup>289</sup> investigated the chlorinated resins prepared by bubbling chlorine into p-cymene at temperatures above 25°C. Metallic aluminum, iron and zinc were used as catalysts. Chlorine substitution takes place in the side chains and the cymyl chlorides condense, splitting out hydrochloric acid. The reaction is catalyzed by the metallic chlorides formed by the action of hydrogen chloride on the particular metal used. The resins prepared in this manner contain 10-30 per cent chlorine. Groggins also formed resinous substances in a similar manner by chlorinating mixtures of p-cymene and other aromatic or aliphatic compounds. The resins were found to be insoluble in acids, alkalies and ethyl alcohol, but soluble in p-cymene, o-dichlorobenzene, turpentine, carbon disulphide and, to a lesser degree, in petroleum distillates. The resin solutions were recommended for use as lacquers or in treating railroad ties, telephone poles or marine piling.

In addition to chlorinated biphenyl and naphthalene resins, other chlorinated waxes or oils yield flame-proof, insulating materials.<sup>290</sup> Asphaltic oils, fish oils, waxes and coal-tar are employed for this purpose. Blakeman<sup>291</sup> treated drying oils, paraffin wax, naphthalene and various other raw materials with chlorine and introduced the chlorinated product into paints. A mixture of chlorinated asphaltum and chlorinated vegetable oil, the latter serving as a toughening agent, was employed by Wickenden<sup>292</sup> in paints and varnishes. For example, 10-20 per cent of cottonseed oil and petroleum asphaltum or pitch melting at 120°C. were mixed and chlorinated in a solution of carbon tetrachloride until the chlorination was complete. The solvent could be removed by distillation. A stable, highly chlorinated train oil for use as paint or binding agent was produced by treating exhaustively-chlorinated train oil with air or an inert gas until only a faint hydrogen-chloride reaction persisted. The temperature during the process could be raised to 70°C.<sup>293</sup> Air containing ammonia was then passed in and a small quantity of a difficultly volatile amine was added.

Resinous materials may be obtained by chlorinating finely divided bituminous coal.<sup>344</sup> The method consists of passing chlorine through the powder or a suspension of it in a liquid and then extracting the product with a solvent. Finely divided lignite in the presence of water gives a resinous substance which may be used as a paint or a varnish.<sup>345</sup> Lignic acids give, on chlorination, resins which are soluble in acetone and amyl acetate. The films left by the evaporation of the solvent are hard, lustrous and tenacious.<sup>346</sup> The action of a solution of sodium hypochlorite saturated with chlorine on Cassel humic acid converts 70 per cent of it into a bright yellow humic acid which contains chlorine. The rest is highly polymerized.<sup>347</sup> In order to raise the softening point of coal-tar pitch, Balle chlorinated it at high temperatures in the presence of carriers.<sup>348</sup> The products were hard and lustrous. They had a conchoidal fracture and a softening point of 100-140°C. Zimmer<sup>349</sup> fused hexachloroethane and esters of fatty acids with tar or pitch in order to make a semi-fireproof coating. The adhesiveness of tar intended for road-making material is said to be increased by chlorination.<sup>350</sup>

Costeanu<sup>351</sup> has reported that when benzene and excess iodine were heated gradually to 600°C. in a sealed tube, a black, nacreous, infusible mass was formed. It had a composition corresponding to  $C_{10}H_{22}I$  and was not attacked by mineral acids. In the preparation of 3,5-di-iodo-4-hydroxydiphenyl sulphide, much tarry material was obtained when an aqueous ammonia solution of p-hydroxy-diphenyl sulphide was combined with an iodine solution.<sup>352</sup> The diazonium salt of the corresponding 2,6-di-iodo compound also gave an uncrystallizable substance when added to dilute sulphuric acid. Bromination of 9-benzylanthracene produced a resin,<sup>353</sup> and coating compositions which could be sprayed have been prepared by chlorinating m-styrene. In the latter case, the products with the largest content of chlorine have the lowest viscosities and the highest melting points.<sup>354</sup> 6,8-Tetradecadiyne, treated with bromine at room temperature, yields  $(C_6H_4CBr=CBr-)$ , with resinification. At 5°C. a yellow liquid is obtained which, on distillation, gives 1-bromoheptyne and a resin.<sup>355</sup> The formation of much tar was observed by Perkin and Stone<sup>356</sup> in the bromination of 2,4-dimethylbenzoyl bromide. They also report that addition of potassium cyanide to di(bromoethyl)benzoic acid furnished a small quantity of a red gum.

The fluorination of organic hydrocarbons has been studied by Bockemüller. Although in some cases he obtained fluoro compounds, in other instances resinification occurred. Resins also accompanied most of the identified products. As fluorinating agents he employed free fluorine,<sup>357</sup> lead tetrafluoride<sup>358</sup> and aryl iodide fluorides,  $R-IF_2$ .<sup>359</sup> Benzene, 1,1-diphenylethene, phenylethene, anthracene, phenanthrene and naphthalene were all found to give tars. The substituted compounds,

bromobenzene, m-dinitrobenzene, anisole, hydroquinone dimethyl ether and 3-phenylpropenoic acid behaved similarly.

Both bromo- and chloroanthraphenone resinify when boiled with a mixture of acetic and sulphuric acid.<sup>300</sup> Bromination of benzyl anthracene results in a resin as does the decomposition of benzyl dihydro-anthraquinyldipyridinium dibromide with water.<sup>301</sup>

Substances which may be utilized in the preparation of tanning agents were produced by chlorinating the black material obtained by steam-distillation of sulphuric acid sludge from the refining of benzene.<sup>302</sup> Highly chlorinated stable products which were considered as substitutes for natural resins or as tanning materials have been prepared from waste sulphite cellulose lye.<sup>303</sup> The waste

FIG. 155.—Flow Diagram for the Chlorination and Dechlorination of Cracked Petroleum Tar. (S. C. Fulton.)

liquor, evaporated without application of heat to a concentration of about 25 per cent, was treated while hot with chlorine gas for 2 hours. The resulting precipitate was separated and treated with a chlorate and hydrochloric acid. The product contained about 20 per cent chlorine.

A process for producing resins by chlorinating the polymeric constituents of cracked petroleum distillates has been developed by Morrell and Egloff.<sup>304</sup> Such constituents, after being separated from the distillates, were mixed with phenols, cresols, tar acids or other compounds, then heated to 300°F. and chlorine introduced until the mixture became relatively viscous.

According to Fulton,<sup>305</sup> a cracked petroleum fraction boiling between 300-660°F. (1 mm. pressure) may serve as the raw material for synthetic resins. (See Fig.

<sup>305</sup> S. C. Fulton, U. S. P. 1,981,824, Nov. 20, 1934, to Standard Oil Development Company; *Chem. Abs.*, 1935, 29, 589.

155.) Chlorine is bubbled through the distillate, while it is agitated at room temperature, until 10-15 per cent is absorbed. Distillation of the product eliminates chlorine as hydrogen chloride and also any volatile oily constituents. Only traces of chlorine are found in the residue, which is dissolved in naphtha, filtered and the solvent evaporated. A lighter-colored resin may be obtained if the solution is treated with sulphuric acid and neutralized before removal of the solvent.

When added in amounts as low as 0.5 per cent the following substances are said to improve the film strength of hydrocarbon oils: the chlorinated derivative of stearic acid and diphenylene oxide, the product from chlorinated lard oil and naphthalene, condensate of 2 halogenated fatty acids or esters or of chlorinated stearic acid and chlorinated paraffin, halogenated diphenylene oxide, chlorinated ethyl oleate, and the condensation product of chlorinated wax with sodium ethoxide.<sup>300</sup>

Keller and Münz<sup>307</sup> have produced compounds which ranged from a viscous oil to plastic materials, and which were said to be colorless and sticky, by chlorinating or brominating fatty acids. Among the acids used by them were ricinoleic, oleic, stearic and dihydroxystearic acids. Pungs<sup>300</sup> suggested chlorination of oxidized paraffin. The resin so obtained was hard, flexible and yellow, with a chlorine content of 55 per cent. It could be further hardened by heating at 110°C.

In order to resolve (break) mineral oil emulsions, Lerch<sup>300</sup> used the reaction product of sulphonated cottonseed oil with a chlorination product of the polyolefin, cyclopentene or cyclohexene series.

A waterproof coating composition may be prepared by dissolving chlorinated wax (containing less than 30 per cent chlorine) in a solvent, e.g., turpentine or solvent naphtha.<sup>370</sup> Incorporation of other materials, for example ceresin or lamp-black, renders the coating capable of taking a high polish.

By removing halogen atoms from halogenated paraffin through heating with aqueous alkalis, various lubricating oils and tallowy substances may be produced.<sup>371</sup> The products contain halogen and hydroxyl groups as well as unsaturated linkages. If more than 9 halogen atoms are in the original molecule, based on an average molecular weight of 367, they may be removed by heating in an autoclave for 10 hours at 150-160°C. The product is a drying oil.<sup>372</sup> Rebs has made a pitch by a similar method.<sup>373</sup> Diphenylmethyl ethyl ether, obtained by refluxing diphenylchloromethane with ethyl alcohol, reacts with hydrogen chloride giving a considerable quantity of dark brown gum.<sup>374</sup> Similar products were found when sym-tetraphenyldimethyl ether was boiled with hydrochloric acid.

One of the compounds formed by treatment of 1,4-diphenyl-2-butyne-1,4-diol

## Chapter 57

### Plastic Sulphur

Elemental sulphur possesses properties which closely resemble those of resins and has been used as a binder in molded products. Although this use of sulphur has not been as important as that of many other materials, yet the possibilities of its development warrant its inclusion here.

Sulphur is chemically different from synthetic resins, but its hardness, vitreous fracture and melting point cause it to resemble them rather closely. At normal temperatures and pressures, sulphur crystallizes in the rhombic system. At 95.4°C., this rhombic form is in equilibrium at atmospheric pressure with a monoclinic modification. With the absorption of something over 100 cal. of heat for each 32 g., rhombic sulphur is converted into the monoclinic.<sup>1</sup> Both of these crystalline modifications<sup>2</sup> have a molecular weight corresponding to  $S_8$ . Above the melting point, as the temperature rises, an amorphous sulphur ( $S_\mu$ ) is formed, and the liquid which was originally yellow increases in viscosity and darkens in color. The maximum viscosity is reached in the neighborhood of 200°C. The change from liquid sulphur to amorphous or plastic sulphur begins at about 160°C., however, the transition point can be substantially raised by the addition of foreign substances. Triphenylmethane, for instance, raises the transition point to 200°C.<sup>3</sup>

The accompanying graph of the viscosity of molten sulphur (on a semi-logarithmic scale) shows the change of this property with change of temperature (see Fig. 156). Presumably the course of the curve is profoundly influenced by polymerization of the element. The data<sup>4</sup> are dependent on the time of heating and the amount of gas or other impurities included in the sample. Hence the curve may not be strictly accurate.

Elemental sulphur in massive form has a marked resistance to acids, to oxidation and to weathering influences. Its hardness ranges from about 1.5 to 2.5 (Mohr scale), and its melting point is high enough to make it useful for many purposes. It possesses fairly good electrical and thermal insulating qualities.

Sulphur may be colored<sup>5</sup> red or brown and when so colored very closely resembles some resins. Colored sulphur castings have been prepared by heating

<sup>1</sup> R. Abegg, F. Auerbach and I. Koppel ("Handbuch der anorganischen Chemie," S. Hirzel, Leipzig, 1927, IV (1), 152) give 3.13 cal. per g. From the equations of G. N. Lewis and M. Randall (*J.A.C.S.*, 1914, 36, 2469) the value calculated is 105+ cal. per gram-atom.

<sup>2</sup> Various modifications of the related element selenium have been obtained by S. Astin, A. C. C. Newman and H. L. Riley (*J.C.S.*, 1933, 391). More complete information on the forms of selenium is found in R. Abegg, F. Auerbach and I. Koppel, "Handbuch der anorganischen Chemie," S. Hirzel, Leipzig, 1927, IV (1), 1, 693.

sulphur with any suitable addition substance to about 300°C., cooling the mixture to a casting temperature of 140-180°C., adding the coloring matter and then casting in the usual manner.<sup>6</sup> Sulphur as mined often contains a small amount of organic impurities which discolor it so that it may be almost any shade from light yellow to dark brown.<sup>7</sup> Kobbe<sup>8</sup> suggests the use of a variety of sulphur-soluble azo dyes for coloring sulphur orange, brown, red, green and black.

Because of its tendency to crystallize, untreated sulphur has very little prospective value in liquid coating compositions. That is, a solution of sulphur when

FIG. 156.—Change in Viscosity of Sulphur with Temperature. Dotted line represents data by L. Rotinjanz (*Z. physik. Chem.*, 1908, 62, 609) and solid line data by C. C. Farr and D. B. Macleod, *Proc. Roy. Soc. (London)* A, 1920, 97, 80.

applied with a brush to a surface and allowed to dry forms a crystalline coating of no particular value. Also, if applied to metals or to other materials which are readily affected by acids, the coating may have a deleterious effect because of the possibility of acids forming by its oxidation. Although finely ground sulphur is practically unaffected by air<sup>9</sup> at 60-80°C., flowers of sulphur are readily oxidized at even lower temperatures. However, these two forms of sulphur have been used in paints and varnishes to cover surfaces with anti-fouling or antiseptic

coatings.<sup>10</sup> Furthermore, it has been stated that 40 parts of cement, 5 parts of mica, and 5 parts of aluminum in 50 parts of molten sulphur give an acid-resisting surface.<sup>11</sup> Another coating which has been suggested consists of a mixture of sulphur and pitch.<sup>12</sup>

Elemental sulphur has certain fields of application which appear to be promising. However, its use is restricted because its desirable properties are offset by its brittleness and its tendency to crystallize. Plastic sulphur holds promise of greater usefulness than crystalline sulphur, since it is somewhat similar to rubber. Trillat and Forestier<sup>13</sup> have shown that plastic sulphur, prepared by heating sulphur to a temperature above 230°C. and then pouring it into cold water, stretches upon rapid drawing to a permanent lengthening of 800-1000 per cent and, at the same time, its physical properties such as transparency and elasticity are changed. The sulphur was amorphous before drawing and crystalline afterward, but the crystalline structure was not the same as that of ordinary orthorhombic sulphur. They have also shown that x-rays stimulate the recrystallization of plastic sulphur. The stress-strain curves for thin filaments of plastic sulphur and of raw rubber have been determined by Strong,<sup>14</sup> and there is some similarity between the two series of curves. Hammick and Zvegintsov<sup>15</sup> suggested that amorphous sulphur is a gel and confirmed this view by observing the Tyndall effect in pure molten sulphur. Like many other substances, if plastic sulphur is kept at a sufficiently low temperature it will not crystallize. Mondain-Monval found that for sulphur this temperature was -29°C.<sup>16</sup>

Above 160°C., sulphur is stable in an amorphous form, mixed probably with small amounts of the two crystalline modifications. Sudden cooling yields a rubbery, elastic material which is unstable at ordinary temperatures and retains its elasticity normally for only a few hours after cooling below the transition temperature. The author has made a number of experiments on the problem of retaining sulphur in a plastic condition and believes that it will be possible to make use of sulphur in this form commercially. Although molten sulphur combines with many organic substances, the larger number of them are not readily soluble therein. The products made by treating phenol or its homologues with sulphur chloride<sup>17</sup> are among the few that dissolve readily in molten sulphur. These retard pronouncedly reversion from the plastic to the crystalline form.<sup>18</sup> Cumarone resin has also been used with sulphur to maintain it in a plastic condition. For example, Grant and Farren<sup>19</sup> employed cumarone resin and sulphur which had been fused together, either with or without a finely divided filler, as a sealing and insulating composition. They reported that the crystallization of sulphur in this mixture was completely prevented. Certain types of cumarone resin when used for rubber compounding cause "blooming" when the unvulcanized rubber stock is stored, but it has been found that<sup>20</sup> this difficulty can be minimized if from 15 to 20 per cent of sulphur is dissolved in the resin before compounding. The

solubility of sulphur depends to some extent on the melting point of the resin. Endres<sup>21</sup> proposed a method of avoiding sulphur bloom in rubber compositions by using plastic sulphur in which the content of rhombic sulphur had been reduced to less than 1 per cent by extraction with carbon disulphide.

Deines believed that the only amorphous form is the solid sulphur which is insoluble in carbon disulphide. He reported that highly sulphurized hydrogen persulphides caused the earlier investigators to come to erroneous conclusions<sup>22</sup> as to the number of amorphous forms.

A stable form of plastic sulphur has been made by heating equal parts of sulphur and antimony trichloride to 400°C. under pressure and then rapidly cooling the melt by pouring it into cold water.<sup>23</sup> This product when mixed with wood tar, coal tar and paraffin wax served as a binder for molded electrical insulation. When approximately equal parts of sulphur and selenium are heated together above the melting point of selenium a cherry-red compound, selenium sulphide

<sup>21</sup> Courtesy Texas Gulf Sulphur Co.

FIG. 157.—Loading Sulphur from One of the Vats at the Texas Gulf Sulphur Company Mine.

is formed.<sup>24</sup> When cooled to room temperature this sulphide forms a black, elastic mass, which remains in the same condition for several days and which gradually becomes so hard and brittle that it may be ground to an orange-red powder melting at about 100°C. This change into a hard, brittle state takes place in about half an hour if the elastic mass is maintained at a temperature of 80-90°C. Nordlander believes that this sulphide in the elastic state is highly polymerized and that it becomes hard and brittle through depolymerization. Selenium sulphide, used as a binder in forming gears and similar products, possesses two noteworthy features. It is unaffected by water or by concentrated acids (excepting nitric acid), and, although it sets to a hard and dense material at 80-90°C., it will

revert to the plastic state if heated to about 110°C. A sulphide exhibiting similar properties is obtained from tellurium.

Wax-like substances may be incorporated with sulphur to modify its properties. Chlorinated naphthalene,<sup>25</sup> for example, has been melted with sulphur to produce a hard and porcelain-like mixture. This mixture has good adherence when applied to metallic or other surfaces. A sulphur composition, made by blending a small proportion of sulphur with waxes or resins,<sup>26</sup> has been proposed as a binding agent in plastic compositions and as a floor wax. When 4 parts of dark-colored carnauba wax and 1 part of rosin are fused with 0.1 part of sulphur and then cooled, the product is light in color, opaque and without a prominent waxy appearance. If sulphur is omitted, the resulting material is dark in color and slightly translucent. Rosin esters when treated in a similar manner show an even more pronounced lightening in color due to the presence of the sulphur. On the other hand, the addition of 0.1-1.0 per cent of rosin to molten sulphur makes the product less liable to dust explosion on grinding, and the powdered mixture does not cake on standing, making it useful as an insecticide.<sup>27</sup> A mastic composition to be used in laying floor blocks has been prepared from a sulphur-rosin mixture containing 15-25 per cent of a lubricating oil.<sup>28</sup> A mixture of cashew nut-shell oil and sulphur has been suggested also as a plastic.<sup>29</sup>

A rubber-like material may be prepared in the following manner:<sup>30</sup> Equal parts of hardened rosin and boiled oil are heated together until the rosin is melted and thoroughly incorporated with the oil. An equal weight of sulphur balsam (consisting of 3 parts of boiled oil and 2 parts of sulphur) is added and the resulting mixture heated to 300°F. On cooling, an elastic product is obtained which may be employed as a waterproofing agent.

Myers<sup>30</sup> made a tough and non-brittle cement by mixing 1 or 2 grains of arsenic per lb. of sulphur. The mixture was applied while it was fluid and was especially designed to anchor a vitreous facing to brick or similar materials. Hamor and Duecker prepared relatively stable plastic sulphur by rapidly cooling a solution of phosphorus sulphide in sulphur from above 200°C. More than 10 per cent of phosphorus sulphide was used.<sup>31</sup> Arsenic and thallium, or their oxides or sulphides, also act as stabilizers.<sup>32</sup> Olefin polysulphides are said to exert a similar effect.<sup>33</sup>

The consideration of sulphur as a binding agent is a subject seemingly unrelated to synthetic resins. However, its cheapness coupled with its other desirable properties has led to its use in various ways where the cost of higher-priced, fusible binders is prohibitive. The addition of a number of materials (particularly chlorinated compounds) has been shown to retard or to prevent the burning of sulphur.<sup>34</sup>

The author has made various molded articles by hot pressing mixtures of

sulphur and fillers. Although these articles had neither the strength nor the surface finish common to resin-containing products, it was found that the compositions had little or no effect on steel molds. Prior to this investigation the criticism that sulphur would blacken the molds had been advanced.

Darrin and others have made a study of what he has termed introfiers or impregnation accelerators.<sup>55</sup> According to him, when an introfier is added it changes the fluidity and the wetting properties of the impregnating material and so increases the penetration. Introfaction cannot be attributed solely to a thinning action, since the amount of introfier required is often very small, and its mechanism is not understood. Darrin states that different classes of substances require different types of introfiers; for instance, a sulphur introfier must have a molecular structure which contains at least two benzene rings. Naphthalene and its derivatives are good sulphur introfiers, and biphenyl, benzyl ether and carbazole are reported to have been used with satisfactory results. The Aroclors are also suggested as introfiers. One difficulty which might be encountered in using them is their "chemical odor."

Some method similar to those which have been discussed for maintaining sulphur in the plastic form may lead to its more extensive use in molded articles as a binding agent where a certain degree of elasticity is required. Bleecker made an impervious, chemically-resistant material by using as a binder for inert fillers sulphur so finely crystalline as to be nearly amorphous. Artificial graphite, sand, coke and pulverized slate were some of the fillers employed.<sup>56</sup> He prevented the growth of large sulphur crystals by rapidly cooling the molten sulphur-filler mixture under pressure, and also by adding such substances as coal-tar pitch or analogous hydrocarbons which react with the molten sulphur. This material could be used in making pipe linings, conduits and machine parts. The products were impervious to liquids and gases and were highly resistant to the action of acids and other chemicals.

Wood has been preserved and strengthened by impregnation with a molten-sulphur solution of a toxic material, e.g., arsenic and phosphorus sulphides.<sup>57</sup> The use of sulphur-soluble, organic arsenic compounds is also recommended.

The art of molding sulphur goes back more than sixty years and from time to time has been commercially important. The cheapness and low melting point of this element, coupled with its hardness, resistance to corrosive action and water, and its electrical insulating value, have allowed it to occupy a not unimportant place in commerce. Brittleness coupled with a high coefficient of thermal expansion and its pronounced shrinkage on solidification have prevented its wider usefulness.

The applications in which its shortcomings are partially overcome may be divided into two principal groups: the manufacture of casting compositions formed by dilution with suitable materials, insoluble in molten sulphur, to overcome the high shrinkage and to bind the brittle sulphur crystals together; and the impregnation of porous materials with molten sulphur to increase their strength and reduce their porosity.

In casting or molding compositions containing sulphur, the more common

<sup>55</sup> M. Darrin, U. S. P. 1,644,711, Oct. 11, 1927, and 1,962,003, June 5, 1934, to F. N. Burt Co.; *Chem. Abs.*, 1927, 21, 4036; 1934, 28, 4858. U. S. Reissue 17,867, Nov. 11, 1930; *Brit. addition is carbon in the form of anthracite coal,<sup>33</sup> graphite<sup>34</sup> or coke,<sup>35</sup> either ground or reduced to colloidal particles.<sup>36</sup> Numerous inorganic fillers have been proposed, such as powdered metals,<sup>37</sup> steatite,<sup>38</sup> bentonite,<sup>39</sup> asbestos,<sup>40</sup> silica,<sup>41</sup> and a mixture of pumice, sand, magnesium carbonate and asbestos.<sup>42</sup> Sawdust,<sup>43</sup> dried powdered peat,<sup>44</sup> wood flour,<sup>45</sup> cassava starch,<sup>46</sup> casein<sup>47</sup> and refined cellulose<sup>48</sup> have been suggested as organic fillers.

As examples of the methods for preparing and casting sulphur compositions, mention may be made of those used by Kobbe<sup>49</sup> and Barnes.<sup>50</sup> The latter pulverized both sulphur and anthracite coal to impalpable powders. Ten parts of the pulverized sulphur were mixed with fifty of powdered coal and the mixture heated until it was fluid enough to pour. Kobbe recommended melting the sulphur and mechanically incorporating comminuted silica the grain size of which was not uniform, but varied as is shown by the following screen analysis (Table 63).

TABLE 63.—Screen Analysis of Silica.

	Per Cent
Held on 80 mesh.....	7.2

Passing 200 mesh, held on 320.....	19.0
Passing 320 mesh.....	43.2

He used approximately equal weights of silica and sulphur since this represented a good balance between too much silica with consequent lack of fluidity and too little silica with consequent lack of strength. The product was light in color and possessed a tensile strength of about 623 lbs. per square inch. The addition of alkali to the melt<sup>51</sup> and the use of aluminum molds<sup>52</sup> have been proposed as means of preventing the casting from sticking to the mold. These sulphur compositions have been molded into a variety of shapes, used as luting or sealing cements,<sup>53</sup> and applied on concrete to form a protective coat against acids.<sup>54</sup>

The investigations of Duecker<sup>60</sup> have shown that the strength of sulphur-sand cements depends mainly on two factors: the per cent voids in the aggregate, and the proportion of sulphur. The effect of the first factor is clearly illustrated by comparing two mixtures possessing the optimum amount of sulphur; the one with sand containing 32.5 per cent voids is 20 per cent stronger than the one with sand having 34.8 per cent voids. This difference in strength is to be expected in the light of data on concrete. Regardless of the grading of the sand, cements of greatest tensile strength are obtained by mixing 40 per cent of sulphur with 60 per cent of sand, and an increase or decrease in amount of sulphur results in a marked loss of strength. Although this is true, more than 40 per cent sulphur is used commercially in order that the cement flow easily. One material that has

FIG. 158.—Apparatus for Continuously Impregnating or Coating Various Materials. Paper or fabric (from the roll on the left) passes through a sealing fluid into a vacuum chamber, over a heating roll, thence through the impregnating solution and out via squeeze rolls to a drying chamber. The sealing liquid is usually mercury, and the central heating-roll is warmed by an internal circulation of steam under pressure. (O. Minton.)

a marked influence on the workability is carbon black. It retards settling of the aggregate and increases the strength of the cement. The latter property is shown by the fact that a cement containing 70 per cent sulphur has its tensile strength increased from 405 to 670 pounds per sq. in. by replacing 5 per cent of the sand with carbon black.

Sulphur has been used to impregnate articles made of porous material to increase their strength, to make them rigid,<sup>61</sup> to alter their electrical properties,<sup>62</sup> to render them resistant to water and corrosives and, as in the case of wood, to preserve them. The fibrous liners that come in contact with rubber sheets have been impregnated with sulphur to prevent their adhesion to the rubber.<sup>63</sup> The

<sup>63</sup> H. A. Endres, U. S. P. 1,808,394, Oct. 19, 1929, to Goodyear Tire & Rubber Co.; *Chem. Abs.*, 1927, 21, 195. H. J. Conroy and R. A. Hayworth, U. S. P. 1,603,570, Oct. 19, 1926, to Goodyear Tire & Co.; *Chem. Abs.*, 1927, 21, 195.

favorite materials for impregnation may be divided into inorganic (portland cement,<sup>64</sup> plaster of paris,<sup>65</sup> gypsum plaster<sup>66</sup> and diatomaceous earth<sup>67</sup>) and organic (paper,<sup>68</sup> molded paper pulp<sup>69</sup> and wood<sup>70</sup>).

The method in general consists in mere immersion of the article in molten sulphur held at the proper temperature to give the desired impregnation and viscosity.<sup>71</sup> Various materials, such as turpentine,<sup>72</sup> may be added to the sulphur to alter its viscosity and increase impregnation, and pressure and vacuum applied alternately have been suggested to increase the penetration. Ellis,<sup>73</sup> however, sprayed fiber board with an emulsion of sulphur, dried and pressed at about 150°C. Another method, which has been proposed, for incorporating sulphur into fibrous materials is to saturate the material with sodium-polysulphide solution followed by acidifying. This precipitates the sulphur throughout the mass and the process is finished by hot pressing.<sup>74</sup>

The chewing gum named "Chex" consists of sulphur mixed with a vinyl resin as base.<sup>75</sup> A paste of dextrin and selenium (notably the gray form of the element) has been used as a fire-proofing agent in electrical insulation.<sup>76</sup> A mixture of sulphur, selenium, and paper or cloth when pressed in molds and heated gives acid-resisting products.<sup>77</sup>

More extensive discussions of these applications of sulphur and the properties of the resulting materials are given by Kobbe,<sup>78</sup> Wilkinson,<sup>79</sup> Bates<sup>80</sup> and Moll.<sup>81</sup> The use of sulphur for impregnating wood to resist decay and insect attack is described by Bresser<sup>82</sup> and English.<sup>83</sup> A colloidal dispersion of sulphur in a dextrin solution with a  $p_H$  of 7.6 has been recommended as a therapeutic agent for intravenous injection.<sup>84</sup>

## Chapter 58

# Sulphur-Olefin Resins

The reaction of the halogen addition products of the lower olefin hydrocarbons, especially ethylene dichloride, with sulphides of the alkali and alkaline earth metals has been found to give resinous bodies. Some of these resemble rubber in being elastic and resistant to wear. To an extent they are even superior to rubber since they are not affected by many solvents nor by ozone. However, such plastics have one disadvantage, they contain an impurity with an unpleasant odor, but for some uses this is not necessarily a serious handicap.

### THEORETICAL RESEARCHES

The olefin sulphides attracted considerable attention during the last century and, by 1850, two different forms of ethylene sulphide had been isolated. The first was a white amorphous solid, insoluble in the common solvents, and was obtained by Löwig and Weidmann<sup>1</sup> through the reaction of alcoholic potassium sulphide on ethylene dichloride. Crafts<sup>2</sup> found that this compound distilled at 200°C., yielding a crystalline distillate having a composition corresponding to  $C_2H_4S$ . The latter sulphide was soluble in carbon disulphide, ether, alcohol and benzene. Husemann<sup>3</sup> synthesized the same substance by heating ethylene dibromide with ethylene trithiocarbonate ( $C_2H_4CS_3$ ) at 150°C. Based on vapor density determinations, the double formula,  $(C_2H_4)_2S_2$ , was assigned to the crystalline compound. Corresponding methylene and propylene sulphides were also prepared. In 1886, Masson<sup>4</sup> studied these two forms of ethylene sulphide and showed that both could be isolated by steam distillation from the reaction products of either method of preparation.

Meyer<sup>5</sup> converted the amorphous sulphide into the crystalline by prolonged boiling with phenol. The latter was removed at the end of the reaction by extraction with alkali. A new and permanently amorphous form of ethylene sulphide was also obtained by boiling ethylene dibromide with concentrated aqueous potassium sulphide. In appearance and solubility this product resembled the other amorphous sulphide, but it differed in that it could not be converted into the crystalline dimer by boiling with phenol. It is probable that this material was among the first synthetic plastics, although it was years before the commercial possibilities of such bodies were realized.

Monomeric ethylene sulphide is a liquid (b.p., 55-56°C.) which polymerizes easily. It is prepared by the action of sodium sulphide on chloroethyl thiocyanate and not by the interaction of an olefin halide and an alkali sulphide.<sup>6</sup> The homologous  $\alpha,\beta$ -thiopropane and  $\alpha,\beta$ -thiobutane<sup>7</sup> are reported as being more stable, whereas

<sup>7</sup> M. Delepine and P. Jaffoux, *Compt. rend.*, 1921, 172, 156; *J.C.S.*, 1921, 120 (1), 156.

trimethylene sulphide<sup>8</sup> and tetramethylethylene sulphide<sup>9</sup> are polymerized by strong acids. These monomeric compounds have all been formulated as containing ring structures.

Compounds of structure similar to the dimeric ethylene sulphide have been prepared by Tucker and Reid<sup>10</sup> through the action of olefin dihalides on 1,2-ethanedithiol. Both monomeric disulphides and polymeric amorphous materials, were isolated. The following formulas were assigned to the two types of compounds:

Other investigators have also obtained related products. For example, pentamethylene tetrasulphide,

has been isolated by Chakravarti and Saha<sup>11</sup> from the reaction product of 1,2-ethanedithiol on dichloroacetic acid. Thiols of the type,  $\text{HS}-(\text{C}_n\text{H}_{2n}-\text{S})-\text{C}_n\text{H}_{2n}-\text{SH}$ , have been found as by-products in the synthesis of olefin dithiols from olefin halides and alcoholic potassium acid sulphide.<sup>12</sup> Oxidation of p-benzenedithiol with ferric chloride gives an amorphous polymer which, when heated with copper, yields the dimeric compound,  $(\text{C}_6\text{H}_4)_2\text{S}_2$ .<sup>13</sup> Morgan and Burstall<sup>14</sup> have prepared seleno compounds analogous to the olefin sulphides.

As some of the commercial sulphur resins are polysulphides, Thomas and Riding's work on the alkyl polysulphides should be considered. Ethyl bromide reacts with sodium tetrasulphide, yielding a mixture of diethyl disulphide and diethyl pentasulphide. Potassium pentasulphide, on the other hand, gives practically pure diethyl pentasulphide,  $(\text{C}_2\text{H}_5)_2\text{S}_5$ , which is a nonvolatile oil.<sup>15</sup>

#### PREPARATION OF OLEFIN-SULPHIDE RESINS

The olefin-sulphide resins have been studied by Baer and by Patrick and Mnookin.<sup>16</sup> The former prepared tough, rubber-like masses by the action of sulphur and alkali sulphides on olefin halides.<sup>17</sup> These plastics can be molded and

vulcanized by the same apparatus as is used with natural rubber. Employment of dilute ammonium sulphide as the sulphur-containing reagent resulted in wax-like bodies. Formaldehyde also could be included in the latter reaction, resulting in materials which were reported to be harder than beeswax.<sup>18</sup> According to Baer,<sup>19</sup> the proportion of olefin halide determines the elasticity of the product, whereas he finds that the solubility in carbon disulphide is determined by the sulphur compound used.

Baer did not state whether the resins thus prepared were made through use of the mono- or the polysulphide. In the following cases, the polysulphides are reported to be useful. The rubber-like polymers formed from olefin halides and alkali polysulphides,<sup>20</sup> when heated with an equal weight of raw rapeseed oil, give

Courtesy J. Baer

FIG. 159.—Crude Product from Ethylene Dichloride and Polysulphide.

a factice which is soluble in benzene, chloroform and ethylene chloride.<sup>21</sup> Not only the simple olefin halides, but also such compounds as isoprene dibromide can be used to form these rubber-like substances.<sup>22</sup> Thus, 5 parts of isoprene dibromide were heated with 150 parts of calcium polysulphide solution for 1 hour at 80°C. The product was tough, rich in sulphur and difficultly soluble in many organic solvents. Further, when the condensation product of ethylene chloride and an alkali

polysulphide is dissolved in carbon disulphide and the solution emulsified with latex, the resulting pasty mass can be vulcanized in the cold.<sup>28</sup>

Baer has also produced resins by heating tall oil<sup>24</sup> with alkali polysulphides. The products are soluble in carbon disulphide, chloroform and benzene. They can be used as a substitute for colophony, for caulking ships and in rubber compositions.<sup>25</sup>

Olefin-polysulphide resins have also been prepared by Patrick and Mnookin.<sup>26</sup> For example, sodium sulphide (750 g. of  $\text{Na}_2\text{S} \cdot 9\text{H}_2\text{O}$ ) is dissolved in water and the solution boiled with sulphur (300 g.). This produces a solution which contains principally sodium tetrasulphide. The solution is then diluted with water until its specific gravity at 70°C. is approximately that of ethylene dichloride. The latter (500 cc.) is added and the mixture heated under a reflux condenser at 70°C. A yellow rubbery solid separates which can be purified by repeated boiling with water. A solution of calcium tetrasulphide (prepared by saturating with sulphur a slurry of lime at its boiling point) can be reacted in similar manner with the halogen-addition products of the olefins derived from cracked petroleum gases. The resulting material was stated to resemble ethylene polysulphide and could be made tougher and less odorous by the incorporation of an insoluble metallic soap.<sup>27</sup>

These resins resembled soft rubber and could be worked, molded and rolled into sheets at 130–140°C. They were only slightly soluble in organic solvents with the possible exception of carbon disulphide. When halides of olefins higher in the series than ethylene are used the products are less solid and elastic. Employment of metallic sulphides containing smaller proportions of sulphur results in harder bodies. With ethylene chloride, sodium acid sulphide yields a white, brittle, odorless material; polysulphides ranging from  $\text{Na}_2\text{S}_4$  to about  $\text{Na}_2\text{S}_{7.75}$  give what Patrick terms a "hard plastic" whereas a "soft plastic" is formed by compounds with higher sulphur content. The resins harden with age but can be stabilized by heating at about 140°C. for an hour.<sup>28</sup> Patrick<sup>29</sup> suggested that these bodies be mixed with fillers, pigments and accelerators and used in the vulcanization of rubber. A typical mixture was:

Soft ethylene-polysulphide plastic (83% sulphur).....	39.8 parts
Pale crepe rubber.....	39.8
Zinc oxide.....	16.0
Hardwood pitch.....	4.0
Isopropyl-xanthogenate tetrasulphide.....	0.4

Although no sulphur was included in the compositions mentioned above, it can be employed in admixture with equal weights of rubber and olefin polysulphide to produce a body resembling soft vulcanized rubber. The latter does not show any sulphur bloom even though its content of this element is quite high.<sup>30</sup>

Another product of a similar nature was prepared by producing the polymer in the presence of a dispersing agent. The procedure gave a latex which could be coagulated in the presence of the constituents of the final compounded rubber, or it could be used to impregnate fabrics. The dispersing agent recommended was precipitated magnesium hydroxide, but others such as gelatin, glue and peptized starch were mentioned as possibilities.<sup>21</sup> Thus, 50 cc. of a sodium hydroxide solution containing 290 g. of sodium hydroxide per l. and 100 cc. of a solution of magnesium chloride containing 172 g. per l. were added to 1000 cc. of calcium polysulphide solution. The latter contained a polysulphide of the empirical formula  $\text{CaS}_{4.7}$  and had a specific gravity of 1.272. A semi-gelatinous dispersion of magnesium hydroxide resulted. Then 157 cc. of ethylene dichloride were added in small portions, keeping the temperature down to 66-80°C. until all of the halide

Courtesy J. Baer

FIG. 160.—Product Shown in Fig. 159 After Rolling.

was added. At the end of the reaction the temperature was raised to 80-88°C. until the odor of the halide had disappeared. The olefin-polysulphide plastic formed in this reaction mixture was a latex-like dispersion which settled to the bottom of the container. The supernatant liquid was decanted and the latex washed by decantation until soluble salts were removed.

Olefin-polysulphide resins are improved by hot curing. Patrick<sup>22</sup> has reported that the hot cure can be controlled by adding chlorinated rubber (15 per cent chlorine), chloroprene or metallic halides so that the final product is more resistant to solvent action. It has been found by Ellis<sup>23</sup> that the olefin sulphide resins are greatly improved by forming them in the presence of the substances produced by the action of sulphur monochloride on phenols. The elasticity was considerably increased and the mixed resin was less liable to crumble during milling.

Previous to reaction with an olefin halide, the alkali sulphide solution may be stabilized by refluxing for 15-20 hours. Further modifications include the employment of a water-miscible alcohol and freshly slaked lime. The former increases the solubility of the halide whereas the latter hardens the product. Thus, a hard thermoplastic material is formed by adding 40 g. of freshly slaked lime (in 200 cc. of water) to 177 g. of sodium polysulphide ( $\text{Na}_2\text{S}_{2.2}$ ) in 1 l. of water. The mixture is thoroughly agitated, about 180 cc. of ethyl alcohol are added, followed by 180 cc. of ethylene dichloride at such a rate that the temperature does not rise above 63°C. The product is greenish blue and coarsely granular. It is washed with water and then with 0.5 *N* acid to remove inorganic salts. In washing, the material also loses its color. After drying to constant weight, it can be mixed with fillers and molded at 132-163°C.<sup>24</sup> If one part of "hard plastic" is heated with up to 10 parts of sulphur at 127-132°C. for 3-4 days, a tough, strong, rubber-like material is produced. The color is greenish yellow and no tendency to become crystalline is exhibited.<sup>25</sup>

#### PROPERTIES AND USES OF THE OLEFIN-POLYSULPHIDE RESINS

The olefin-polysulphide resins resemble rubber fairly closely in physical properties and therefore have been suggested as substitutes for it.<sup>26</sup> It should be noted that such products are oil-resistant and this is the main incentive which has led to their study and use.<sup>27</sup> A typical formula for compounding Thiokol A is the following:

Thiokol A . . . . .	100 parts
Diphenylguanidine . . . . .	0.25
Tetramethylthiuram disulphide . . . . .	0.10
Rubber . . . . .	5.
Zinc oxide . . . . .	10.
Carbon black . . . . .	25.
Stearic acid . . . . .	0.50

In this composition, the diphenylguanidine acts as a softener in the earlier part of the mixing, enabling the rest of the ingredients to be added without getting the material overheated. The latter condition is to be avoided as otherwise the odor will be unduly strong. As the other ingredients, especially the stearic acid, carbon black and zinc oxide, are added the mass becomes stiffer. To avoid too great a stiffening, the tetramethylthiuram disulphide is added. It does not act fast enough on Thiokol A to be used as an initial softener, but it differs from diphenylguanidine in that the presence of acids and carbon black does not interfere with its plasticizing action. The rubber is added to decrease the cold flow, to in-

Baer, *ibid.*, 1934, 10, 55 and reply by A. H. Smith, *ibid.*, 1934, 10, 55; *Chem. Abs.*, 1934, 28, 4628, as to priority in the manufacture of these oil-resistant substances.

crease the flexibility at low temperatures and to improve the molding properties. The zinc oxide assists in the heat cure of the product after fashioning, whereas the carbon black increases the strength and further decreases the cold flow. Finally, the stearic acid is added as a mold lubricant.

Such a mixture requires a cure of about 50 minutes at 142°C. to raise the tensile strength and to decrease the cold flow. It will then resist the swelling action of most liquids encountered in industry. Thus, gasoline, motor oil, fuel oil, carbon tetrachloride, Duco Thinner and turpentine cause no dimensional increase after two years' immersion. Dilute acids do not harm Thiokol A. Even strong

FIG. 161.—Mixing Thiokol in Vats.

acetic acid causes no degradation, but oxidizing acids (nitric and chromic) attack the olefin polysulphides.<sup>38</sup> Caustic alkali, but not sodium carbonate, hardens Thiokol A so that it will break on bending. Oxygen and ozone do not attack Thiokol A; samples which were exposed to the weather showed no signs of cracking. Kartzev and Verbo<sup>39</sup> stated that up to 5 per cent Thiokol in rubber mixtures used in automobile tires increased the tensile strength and resistance to wear of the vulcanizates.

The principal disadvantage of the olefin polysulphides is their marked odor.<sup>40</sup> However, as has been previously noted, this has not prevented their being employed for some purposes. Thus, asbestos impregnated with Thiokol A has been used to seal the joint around the edge of the floating roofs of oil tanks.<sup>41</sup> The seal has shown its ability to stand up against sunlight, weathering and sour crude

<sup>38</sup> *Chem. Met. Eng.*, 1932, 39, 318, 654.

oils. A number of applications employ Thiokol A as a protective coating for natural rubber. The latter furnishes the required elasticity, partially neutralizing the cold flow of the polysulphide. In this way gaskets<sup>42</sup> for oil lines, rubber hose for handling petroleum distillates,<sup>43</sup> and printers' rollers and blankets<sup>44</sup> have been made. Again, the olefin polysulphides have been used in the manufacture of insulated cables.<sup>45</sup> Although Thiokol A can be bonded to metal, it is not especially recommended for this. However, Thompson<sup>46</sup> has succeeded in attaching it and other rubber-like materials to rigid surfaces by an intermediate layer of a phenol-formaldehyde condensation product. The latter and other types of synthetic resins have been formed in admixture with olefin polysulphides by dissolving the sulphide in one component of the resin and then adding the other.<sup>47</sup>

#### RESINS RELATED TO THE OLEFIN SULPHIDES

Resins made from the dichlorohydrins of glycerol form a group closely related to the olefin sulphides.  $\beta$ -Dichlorohydrin (2,3-dichloro-1-propanol) is the chloride of allyl alcohol; therefore the sulphides formed from it might be regarded as olefin derivatives. However, the  $\alpha$ -compound (1,3-dichloro-2-propanol) cannot be considered a derivative of an unsaturated alcohol. Nevertheless, both  $\alpha$ - and  $\beta$ -dichlorohydrin are discussed here since they exhibit some similarities.

In 1873, Claus<sup>48</sup> reported that a review of the earlier work of Carius<sup>49</sup> on the formation of glycerol dichlorohydrin had confirmed the formation of sulphur-containing by-products. The method which these investigators used involved the reaction of sulphur monochloride on glycerol.

A 62 per cent yield of purified product was obtained by Claus. This product possibly contained some  $\beta$ -dichlorohydrin although it consisted principally of the  $\alpha$ -compound. The latter has also been prepared in 70 per cent yields by passing gaseous hydrogen chloride into glycerol containing a small amount of acetic acid.<sup>50</sup>

Carius<sup>51</sup> prepared thioglycerols by the action of potassium hydrogen sulphide on the above-mentioned chlorohydrins. The thioglycerols were viscous substances with disagreeable odors. They dissolved in alcohol and lost hydrogen sulphide on heating. Lilienfeld<sup>52</sup> has studied these compounds and especially those formed

by the action of inorganic sulphides on glycerol dichlorohydrin. He believed the reaction to be as indicated in the preceding equation. The cyclic sulphide polymerized with the formation of a disulphide,

The  $\beta$ -dichlorohydrin of glycerol gave analogous products. The original material obtained from the reaction was a viscous fluid. Heat transformed this liquid into a solid, pliable, elastic mass, a conversion which could be carried out *in situ* after impregnating fabric with the thioglycerol. Prolonged heating resulted in a horny body. Lilienfeld intended to use these products as substitutes for rubber or horn and in the manufacture of threads and adhesives.

In his earlier work Lilienfeld used at least stoichiometric amounts of alkali sulphides. Later, resins formed by employing less than the equivalent amount of sulphide (or the corresponding selenium or tellurium compound) were reported as being possible reagents in organic synthesis, and he contemplated using them for medical purposes.<sup>53</sup> Molded articles were made by incorporating urea-aldehyde resins into the thioglycerol compound.<sup>54</sup>

some oil, which could be decanted, were formed. Sulphuryl chloride brought about a similar resinification.

Amino and hydroxy compounds are formed when polychlorinated paraffins are heated with solutions of ammonia or caustic alkali, respectively. If the products still contain chlorine or if they are unsaturated, they will react with sulphur or metallic sulphides to form oils. For example heating hexachlorinated hard paraffin with alcoholic ammonia furnished nitrogenous bodies. Forty parts of this material were mixed with 200 parts of a saturated solution of hydrogen sulphide in 10 per cent alcoholic potassium hydroxide. The mixture was heated at 130-140°C. for 3 hours. The nitrogen-containing product possessed an average of one thiol group per molecule. It was free from chlorine and was more unsaturated than previous to sulphurization.<sup>55</sup> Oxidation of the sulphidic bodies thus obtained yielded sulphonic acids which were said to be applicable in the textile and pharmaceutical industries.<sup>56</sup>

#### OTHER OLEFIN-SULPHUR RESINS

Sulphur dioxide adds to olefin hydrocarbons to form sulphones. The formulas that have been assigned by De Bruin and Staudinger<sup>57</sup> in the case of butadiene hydrocarbons are cyclic sulphones of the general type,

Staudinger obtained these monomeric products by using such anticatalysts as pyrogallol and hydroquinone in order to prevent polymerization. Eigenberger<sup>58</sup> reported that he had obtained two isoprene sulphones of which the less soluble may have been a polymer.

When the simple olefins are placed in a sealed tube with liquid sulphur dioxide, the oxide adds to the double bond, and a white, glassy solid results. The reaction does not take place in the dark, but is complete in a few days if the tube is exposed to sunlight. The products are soluble in chloroform and acetylene tetrachloride. Matthews and Elder<sup>59</sup> stated that these resins may be employed as substitutes for celluloid or may be mixed with the latter material to reduce its inflammability. The heteropolymers of cyclohexene and cyclohexadiene with sulphur dioxide have been prepared by Seyer and King.<sup>60</sup> The reaction with cyclohexene, but not with cyclohexadiene, occurred only in the presence of oxygen. Frederick, Cogan and Marvel<sup>61</sup> studied the condensation product of cyclohexene and sulphur dioxide. They demonstrated that it was a long chain of cyclohexylene radicals separated by sulphone groups. Acetylation showed that there was a hydroxyl group at the end of the chain. From the analysis of the chloroacetate and the cryoscopic determination of the molecular weights of the acetyl and

chloroacetyl derivatives in dioxane, the molecular weight was considered to be approximately 6000. That would correspond to a value of about 39 for "n" in the formula,

The reaction between sulphur monochloride and olefins<sup>65</sup> is strongly exothermic and often yields resinous materials. The addition of sulphur monochloride to 2,3-dimethylbutadiene, both in carbon disulphide, gave an oil after evaporation of the solvent *in vacuo*.<sup>66</sup> Distillation of this oil yielded a solid polymer or decomposition product. Below 100°C., bis(2-chloropropyl) sulphide can be obtained from propylene<sup>67</sup> and a similar compound has been prepared from commercial amylene. The formula, (C<sub>4</sub>H<sub>9</sub>ClS)<sub>n</sub>, was assigned to the latter substance since, on reduction, it formed diamyl disulphide, C<sub>8</sub>H<sub>18</sub>-S-S-C<sub>8</sub>H<sub>18</sub>.<sup>68</sup> Above 100°C., both butylene and propylene are converted into black resins by sulphur chloride. 1-Bromo-2,2'-dichlorodiethyl sulphide,<sup>69</sup> bis(3-iodopropyl) sulphide<sup>70</sup> and bis(chloroacetyl) sulphide<sup>71</sup> all decompose on standing. In an attempt to compare the electronegativities of the two propyl radicals, von Braun and Murjahn<sup>72</sup> treated n-propyl-isopropyl sulphide with cyanogen bromide. Instead of the desired splitting into bromide and thiocyanate, the mass resinified.

Twiss and Neale<sup>73</sup> refluxed ethylene dichloride with a solution of sodium thiosulphate in aqueous alcohol. The product was acidified with acetic acid and heated with hydrogen peroxide, furnishing a rubber-like material. The latter was reported to increase the oil-resistance of rubber compositions.

#### ALDEHYDE-SULPHUR RESINS

The thioaldehydes are simply related to the normal aldehydes. In the thio compound, the oxygen atom of the aldehyde group is replaced by a sulphur atom, giving substances of the general formula, RCHS. A polymer of the simplest member of the series, thioformaldehyde, was described by Fromm and Soffner.<sup>74</sup> This compound (m.p., 216°C.) was furnished by the reaction of hydrogen sulphide

<sup>65</sup> This reaction may be applied to the determination of olefin hydrocarbons. W. F. Faragher, J. C. Morrell and I. M. Levine, *Ind. Eng. Chem., Anal. Ed.*, 1930, 2, 18.

with formaldehyde and was probably a dithiol,  $\text{HS}-\text{CH}_2-\text{S}-(\text{CH}_2-\text{S})_x-\text{CH}_2\text{SH}$ . On treatment with hydrogen chloride, it gave another material which melted at  $247^\circ\text{C}$ . and which was believed to be polythioformaldehyde,  $(\text{CH}_2\text{S})_n$ . The molecular weight of neither of the compounds was determined. Fromm and Soffner believed, however, that it was doubtful that the number of carbon atoms was equal to three.<sup>75</sup>

Borgeson and Wilkinson<sup>76</sup> made a study of the reactions which take place when aldehydes are dissolved in liquid hydrogen sulphide. Benzaldehyde,<sup>77</sup> p-tolualdehyde and cinnamaldehyde all yielded gelatinous products, the general reaction being

A crystalline substance, on the other hand, was isolated in the case of furfural.<sup>78</sup> Further, it has been found that acetaldehyde with hydrogen sulphide in the presence of dilute hydrochloric acid forms monothioparaldehyde. This is converted into  $\alpha$ -trithioacetaldehyde by 2N hydrochloric acid.<sup>79</sup> There are two trithioacetaldehydes, both of which are crystalline compounds. They are represented by the following cis and trans formulas:<sup>80</sup>

The thioaldehydes polymerize rather easily with the formation of resins. In fact, the monomeric thioaldehydes are relatively rare.<sup>81</sup> Renard<sup>82</sup> prepared dithio-trioxymethylene as a hard, wax-like solid melting at  $80-82^\circ\text{C}$ . Delepine,<sup>83</sup> in 1888, observed the formation of a resinous substance in the reaction of ammonium sulphide with formaldehyde. This material was assigned the formula,  $(\text{CH}_2)_5\text{S}_2\text{N}_2$ , and the name pentamethylenediaminedisulphine. It is resistant to alkalies and has been employed in chloroform solution as a coating and impregnant.<sup>84</sup> It can also be used in molding compositions both as a binder and as a plasticizer for other resins.<sup>85</sup> Further, this sulphine and the related selenium compound<sup>86</sup> are stated to be vulcanization accelerators.

Products similar to that produced by Delepine have been studied by Levi.<sup>87</sup> Substituted thialdines were obtained by the reactions of amine sulphides with formaldehyde. For example, aniline<sup>88</sup> condensed with formaldehyde and hydrogen sulphide in the following manner:

The same investigator also isolated substituted ammonium salts of thioacids<sup>89</sup> and polysulphides of substituted thiurams<sup>90</sup> and of aryl isothiocyanates<sup>91</sup> as non-crystalline pitches.

Rubber-like materials have been made by the condensation of formaldehyde with solutions of alkali polysulphides. The resins formed could be milled, compounded, molded and vulcanized in the same manner as rubber.<sup>92</sup> The olefin-sulphide resins mentioned earlier in this chapter were also suggested as possible ingredients in aldehyde-polysulphide compositions. Patrick<sup>93</sup> replaced the aldehyde used in making the latter type of resin with hexamethylenetetramine or polymerized formaldehyde. The mixed aldehydes produced by oxidation of the gases formed in petroleum cracking have also been proposed.<sup>94</sup> In one example, the aldehydic mixture contained approximately 27 per cent formaldehyde, 3 per cent acetaldehyde and a considerable proportion of methanol and small quantities of higher aldehydes and acids. A sodium polysulphide solution was prepared by heating 40 g. of sodium hydroxide with 96 g. of sulphur and 150 g. of water. One hundred seventy g. of the mixed aldehydes were added to the polysulphide solution, and heat was applied to raise the temperature to the bubbling point. The mass was kept at incipient boiling for 4 hours and was then allowed to stand over night. The product after drying was a clear, soft, brownish resin. A variation of the procedure was to add an olefin halide to the aldehyde before reacting it with the polysulphide. A further modification of thioaldehyde resins is to incorporate a sulphur-phenol resin into polymethylene sulphide.<sup>95</sup>

Bruins<sup>96</sup> has prepared polythiofurfural in the following manner: A 3 per cent solution of furfural in water was treated with hydrogen sulphide for 3 hours at 50°C. The emulsion that resulted was coagulated by adding a small amount of hydrochloric acid, producing a rubber-like mass. When furfural is boiled with a solution of sodium polysulphide, a sticky material is formed which becomes firmer and more elastic on washing.<sup>97</sup> A further resinification of furfural is that which is effected by sulphur chloride. However, the resulting body is probably not a true thioaldehyde, since sulphuric and phosphoric acids are also said to produce the same substance.<sup>98</sup>

Dithiofuroic acid and its salts are said to be vulcanization accelerators. The acid has been prepared through the reaction of furfural and sulphuric acid on

aqueous sodium sulphide and sulphur.<sup>90</sup> Staudinger and Reichstein<sup>100</sup> allowed an alcoholic solution of furfural and ammonium acid sulphide to stand for several hours. When the initially formed bis(furylmethyl) disulphide was reduced, a small amount of resin was produced along with furylmethylthiol.

A viscous material results when rubber latex to which soluble sulphides or colloidal sulphur have been added is treated with aldehydes. The latter may either be in solution or in the vapor form. The product is vulcanized after shaping.<sup>101</sup> A similar composition, containing rubber latex, starch, sodium carbonate, a soluble metallic polysulphide and formaldehyde, has been used to render paper water- and grease-proof.<sup>102</sup>

A tanning agent has been made by condensing sulphonated cresol with the reaction product of urea, formaldehyde and ammonium sulphide. The final material had a  $p_H$  of about 5.<sup>103</sup> Urea condenses with thioaldehydes to form an "artificial albumin" from which molded objects have been made. Thus, an aqueous solution of ammonium sulphide (containing 20 g. of the dry salt) was poured on 100 g. of urea. The latter rapidly dissolved and 250 cc. of 40 per cent formaldehyde were added. A quiet reaction took place on heating, resulting in a syrup which, if the water was further evaporated, solidified on cooling to a glass-clear jelly.<sup>104</sup> In this case the sulphine syrup was soluble in water, but if larger proportions of formaldehyde were used the products were insoluble.<sup>105</sup> The latter bodies were liquids and did not solidify on standing. However, they were converted by acid anhydrides into clear, highly refractive solids which were further hardened by contact with warm air. The soluble type of product was rendered insoluble by evaporation or by coagulation with acids and alkalies. It was also produced in the cold by allowing the mixture to stand until a crystalline paste resulted. Contact with metals, especially aluminum, facilitated this conversion. In place of urea, its derivatives and analogues, e.g., guanidine and dicyanodiamide were also used.<sup>106</sup> Related plastic bodies have been made by condensing urea in alkaline solution with an aldehyde and a polysulphide, thiosulphate or polythionate.<sup>107</sup>

Hantzsch<sup>108</sup> reports that partial resmification of acetonyl thiocyanate<sup>109</sup> takes place when this substance is reacted with ammonia. An attempt has been made to determine the halogen in chloro- and bromoacetone by decomposing them with sodium sulphide and titrating the halogen. The method failed, the chief product being a resinous mass from which a little diacetonyl sulphide was isolated.<sup>110</sup>

## Chapter 59

### Sulphur-Phenol and Sulphur-Aniline Resins

Sulphur and reagents furnishing it react with a wide variety of organic compounds. In the case of aromatic hydrocarbons many of the sulphur derivatives so obtained are dyes possessing high molecular weights and non-crystalline structures.<sup>1</sup> On the other hand, phenol forms resinous products not exhibiting the properties of dyestuffs when treated with sulphur or its compounds.<sup>2</sup> Some of the phenol-sulphur bodies have been adapted for molding while others serve as mordants and tanning agents. In spite of their complexity, an insight as to the constitution of these resins may be gained by a consideration of the simpler compounds isolated during the course of the sulphur-phenol reaction.

#### PHENOL-SULPHUR HALIDE RESINS

In 1887, Tassinari<sup>3</sup> reported that the violence of the reaction between phenol and sulphur dichloride made it necessary to dilute the reactants with carbon disulphide and to admix them slowly while cooling. After each addition of sulphur dichloride, the mixture became black but decolorized on standing. A compound, proved to be bis(p-hydroxyphenyl) sulphide, and a resin were isolated from the reaction products. The sulphide was accounted for by representing (empirically) the course of interaction as:

Tassinari concluded that hydrogen was not eliminated from the benzene nucleus inasmuch as acetylated phenol would not react with sulphur dichloride. Hence, he postulated the formation and rearrangement of an unstable intermediate,  $(\text{C}_6\text{H}_5\text{O})_2\text{S}$ . Tassinari also believed the resin to be of the general structure:

for on reduction with hydrogen, it was converted to the corresponding hydroxy thioether,

with the liberation of hydrogen sulphide. Resins were produced with other phenols (p-bromophenol, trichlorophenol and the cresols).  $\beta$ -Naphthol showed more violence in its reaction than  $\alpha$ -naphthol.

In view of the isolated intermediates, it is possible to consider the structure of the phenol-sulphur halide resins as a union of hydroxyphenyl radicals connected through sulphur atoms in the following manner:

Union of phenol nuclei, through sulphur atoms, entirely at ortho positions is not precluded, however. Furthermore, as each of the phenol nuclei has unsubstituted positions (ortho or para), molecular enlargement may also occur by replacing further hydrogen atoms.<sup>4</sup>

**Preparation of Phenol-Sulphur Chloride Resins.** Kuhn,<sup>5</sup> working in the author's laboratory, prepared an alcohol-soluble sulphur resin from "metaparacresol" (commercial cresol) and sulphur chloride. As this product may be regarded as typical of the general class of phenol-sulphur chloride resins, its preparation will be described in rather full detail.

A good quality of "metaparacresol" (1 part by weight) is diluted with an equal volume of toluene and stirred while 1.5 parts of sulphur chloride are added slowly. Hydrogen chloride is given off copiously, and the operation should therefore be carried on under a hood or in an apparatus equipped with absorption media. Heat is evolved during the course of the reaction, and at the end the hot product is blown with air at about 150°C. This treatment removes the solvent (which can be recovered) and also tends to deodorize the resin.

Removal of the odor is usually necessary, since the products contain traces of chlorophenols and other bodies possessing what would popularly be termed a "chemical smell" distasteful to non-chemists. At 150°C. the time required for the air-blowing is 15-30 minutes. A variant of this procedure involves blowing with steam at 120°C. and then baking in thin layers at 125°C. for several hours.<sup>6</sup> The resin is thus hardened somewhat and thoroughly dried. The latter condition is desirable since otherwise solutions of the resin in alcohol and other organic solvents are prepared with difficulty.

As the required initial materials when obtained commercially are not water-white, the resin produced by the action of sulphur chloride on phenols is likely to be colored. Moreover, more or less highly colored by-products are formed. Removal and avoidance of discoloration may be attained by the use of pure reagents, diluents and bleaching compounds. As a further precaution, the reaction vessels should be made of glass, enamelled iron or other substance incapable of contaminating the resin with a colored sulphide. Ellis and Meigs<sup>7</sup> purified their reactants by redistillation and then decolorized with fuller's earth or bone black. Since some color always results even with refined phenol and sulphur chloride, a limited amount of diluent is added to moderate the reaction. Large proportions of diluent tend to decrease the hardness of the resin. Specifically, 300 parts of phenol crystals are dissolved in 250 parts of benzene and a solution of sulphur monochloride (250 parts in 350 parts of benzene) is added slowly with

<sup>4</sup> R. Lesser and G. Gad (*Ber.*, 1923, 56, 963; *Chem. Abs.*, 1923, 17, 3181) observed that when the para position in a phenol is filled and one of the ortho positions has a negative substituent, no reaction takes place with sulphur mono- or dichloride.

<sup>6</sup> Carleton Ellis, U. S. P. 1,557,519, Oct. 13, 1925; *Chem. Abs.*, 1926, 20, 118.

<sup>7</sup> Carleton Ellis and J. V. Meigs, U. S. P. 1,756,818, Apr. 29, 1930, to Carleton Ellis; *Chem. Abs.*, 1930, 24, 3092.

stirring. A creamy-white, bulky precipitate is formed which yields, when dried and pressed, a white, waxy material soluble in alcohol, aqueous sodium hydroxide and hot sodium carbonate solutions.

Water was found to be a satisfactory diluent by Ellis and Meigs.<sup>a</sup> It prevents excessive temperature rises, absorbs the hydrogen chloride formed (thus eliminating the necessity for external absorption apparatus) and seems to produce tougher resins than those given with other diluents. Sulphur monochloride (675 g.) is slowly run into an emulsion of 500 g. of cresol (97 per cent tar acids) in 2500 cc. of water and 300 g. of crushed ice. The resin precipitates as a yellow mass leaving a solution of hydrochloric acid as a by-product. After kneading with hot water, cooling, powdering and drying at 70-80°C., the solid material is largely soluble in alcohol, partly soluble in benzene or cold aqueous sodium hydroxide but dissolves completely in hot caustic soda solution. The resin, however, is unstable to heat, and the acid (which tends to discolor the product) must be removed. Strong bases are not satisfactory, but repeated extractions with a 3 per cent sodium carbonate solution give a stable resin. Calcium carbonate, freed from sodium hydroxide and other strong alkalies, may be employed. Zinc oxide also may serve as an antacid since in this case no undesirable by-products are formed. Iron oxide gives rise to highly colored areas which impair the appearance of the resin. Zinc oxide may be added while the crude resin (immediately after formation) is being kneaded with water or it may be added to an alcohol solution of the partially acid-free and dried material.

If the cheaper grades of phenols, i.e., the commercial types of cresol containing about 25 per cent of tar acids, are to be used, a reducing agent is incorporated in the reaction mixture. Ellis and Meigs employed stannous chloride, sodium hyposulphite and zinc dust, the latter being especially effective. During treatment with finely-divided zinc, hydrogen was evolved and the resin separated was light-yellow in color.

The hardness of the bodies obtained in the phenol-sulphur chloride reaction depends on several variables. Harder resins are prepared by replacing phenol with cresol, using water as a diluent, and by employing higher proportions of sulphur chloride.<sup>b</sup> With organic diluents, softer materials result. It has been found that increase in hardness decreases the solubility, as is shown in Table 64.

TABLE 64.—*Properties of Certain Phenol-Sulphur Chloride Resins.*

Parts of S <sub>2</sub> Cl <sub>2</sub> per 100 of Phenol	Appearance	Solubility
100 . . . . .	Viscous liquid	Easily soluble in alcohols, acetone, ethyl and methyl acetate, benzene and its homologues.
150 . . . . .	Sticky solid	As above.
200 . . . . .	Solid	Less soluble in alcohol, still fairly soluble in esters.
250-300 . . . . .	Hard resins	Progressively less soluble.
300 . . . . .	Hard resin	Not readily soluble in denatured alcohol, soluble in alcohol-benzene, ethyl acetate-chlorobenzene and acetone-toluene mixtures.
350 . . . . .	Hard resin	As above.
400 . . . . .	Not as hard as with 350 parts	

The particular resins described in this table were made by running sulphur

<sup>a</sup> Carleton Ellis and J. V. Meigs, U. S. P. 1,756,810, Apr. 29, 1930, to Carleton Ellis; *Chem. Abs.*, 1930, 24, 3092. See also K. Daimler (German P. 389,360, 1921, to Farb. vorm. Meister, Lucius & Brünig; *J.S.C.I.*, 1924, 43, 800B) who used the products as tanning agents.

<sup>b</sup> F. E. Layman, L. T. Richardson and O. A. Cherry (U. S. P. 1,692,914, Sept. 4, 1928, to Cutler-Hammer Mfg. Co.; *Chem. Abs.*, 1928, 22, 3999) have hardened sulphur chloride-phenol resins by treating them with additional quantities of sulphur chloride.

chloride into molten phenol and were light-yellow to light-brown in color.<sup>10</sup> The softer members of the series have been suggested for use in the preparation of fly paper. Some of the products find application as tanning agents. In varnish-making, the resin derived from 1.33-1.50 parts of sulphur chloride per part of any of the lower phenols is recommended. For the latter purpose, a fairly light-colored and chemically inactive resin is required. A difficulty presents itself here, for the sulphur resins usually contain small quantities of hydrochloric acid which eventually lead to the corrosion of metallic surfaces. Neutralization with bases does not solve the problem since discoloration of the product ensues. Ellis<sup>11</sup> obviated these difficulties by replacing the hydrochloric acid with acetic acid through the addition of sodium acetate. The relatively weak organic acid volatilizes in use leaving the film sufficiently acid to remain light in color, but not enough to be objectionably corrosive. If pigments are to be used in the resin, zinc oxides, lithopone and barytes are preferable to lead compounds, since the latter become blackened through reaction with residual traces of sulphur.

Phenol-sulphur chloride resins have been applied to other purposes than in varnishes and as tanning agents. Ellis<sup>12</sup> employed this type of synthetic product to minimize the crystallizing tendency of sulphur. To achieve this end, crude xylol is dissolved in benzene and reacted with an equal weight of sulphur chloride. The resulting material, after being neutralized and deodorized as described previously, is added to three times its weight of melted sulphur. No indication of the crystalline structure common to sulphur is shown by the composition (which is also ignited with greater difficulty). The sulphur composition may be used to impregnate fiber board and also for molding.<sup>13</sup> A phenol-sulphur dichloride resin can be mixed with cellulose esters and ethers in the manufacture of lacquers, adhesives and yarn.<sup>14</sup> Phenol-sulphur chloride resins incorporated with equal parts of urea-formaldehyde condensation products yield a mixture which is readily fusible and gives a sharp imprint in a mold.<sup>15</sup> This type of composition can also be used as a binder for mica powder and other fillers. Guanidines and other urea derivatives may be substituted for urea in the blend. Inter-resinification, or reaction between the two types of resin, is considered to take place during the molding operation. This is probably due to condensation of phenol with formaldehyde from the urea resin.

Alone, sulphur resins may be employed as flotation reagents,<sup>16</sup> fungicides, tanning agents and rubber preservatives.<sup>17</sup> As the products retain their phenolic groups, they form metallic salts. The calcium, magnesium, zinc and copper salts are only slightly soluble in water and are described as particularly active in the destruction of the fungi *Oidium* and *Peronospera*.<sup>18</sup> Hilbert and Johnson<sup>19</sup> prepared hydroxyphenyl sulphides possessing germicidal properties. The method consists of diazotizing an aromatic amine and condensing with, e.g., the sodium salt of p-methoxythiophenol. On heating, the reaction product decomposes forming p-methoxydiphenyl sulphide which on hydrolysis gives p-hydroxydiphenyl sulphide:

The phenol coefficient (amount of dilution necessary to give the same bactericidal activity as phenol) of p-hydroxydiphenyl sulphide was 115. Tests on rabbits indicated the compound was relatively non-toxic.

Kartaschoff<sup>20</sup> prepared metal derivatives by treating intermediates of the sulphur chloride-phenol reaction with salts of tin, chromium, antimony, zinc, molybdenum, aluminum, manganese or nickel. Tin chloride, however, is the principal reagent. The condensation products possess tanning properties.

**Modifications of the Phenol-Sulphur Halide Resins.** Daimler<sup>21</sup> employed a phenol sulphonic acid in the reaction with sulphur chloride. A solution of the product can be used as a tanning agent. Phenol-sulphur halide resins were sulphonated by Virck<sup>22</sup> in conjunction with an excess of a phenol. The sulphur chloride-phenol resin is treated with concentrated sulphuric acid at 100°C., the temperature is raised to 220°C. and a further proportion of a phenol is incorporated. Excess phenol is expelled *in vacuo* at 240°C. The product is soluble in aqueous sodium carbonate and is precipitated as colorless flakes by acids. Resins of this type may be utilized in the manufacture of lakes with basic dyestuffs. In an earlier method, Virck<sup>23</sup> omitted the addition of phenol during sulphonation. A procedure analogous to the treatment with sulphuric acid is acylation of the resin (during its formation) with acetic anhydride or benzoyl chloride.<sup>24</sup>

Sulphur halides other than the mono- and dichloride also give resins on reaction with phenols. As an example, 2 mols of thionyl chloride are added at 0°C. to a solution of 1 mol of technical cresol in an equal weight of concentrated sulphuric acid.<sup>25</sup> The mixture is poured on ice, and the precipitate formed is separated and heated giving a high-melting, ruby-colored resin soluble in alcohol and aqueous sodium carbonate. McMaster and Ahmann<sup>26</sup> obtained glassy solids of indefinite composition by the action of thionyl chloride with m-hydroxybenzoic acid or with o- and m-cresotinic acids.

According to the work of Hirwe, Jadhav and Chakradeo,<sup>27</sup> hydroxybenzoic acids do not condense readily with thionyl chloride. The presence of a carboxyl group introduces the possibility of forming different anhydro compounds and inhibits the reaction. The difficulties are avoided by employing an ester (such as methyl salicylate) and finely divided copper. The reactions involved in the condensation of methyl salicylate are reported to be as follows:

It is interesting to note that the thionyl chloride is reduced to sulphur monochloride and dichloride before taking part in the reaction. The main reaction product, bis(3-carbomethoxy-4-hydroxy-phenyl) thioether is analogous to the phenol-sulphur halide intermediates.

The properties of sulphur-halide resins may be modified by the addition of various substances in the preparation of compositions to fit particular needs. Votapek<sup>28</sup> mixed the resin with stearin pitch and asbestos to form a molding composition. To 100 parts of a mixture including stearin pitch, coal-tar pitch, gilsonite, castor oil and benzene as modifiers, Cherry and Chosa<sup>29</sup> added 1 part of phenol and 1 part of sulphur chloride. Mordants and wool-resists used in dyeing can be made by incorporating a mixture of sulphur monochloride (5 parts) and stannous chloride (2 parts) with phenol (5.4 parts) at 50-100°C.<sup>30</sup> A 35 per cent solution of sodium hydroxide (10 parts) is stirred in at the end of the reaction. Layman and Richardson<sup>31</sup> prepared sound records from a composition made by heating 10 parts of phenol-sulphur chloride resin and 1 part of white lead at 150°C.

**Use of Formaldehyde as a Modifier.** Modification of phenol-sulphur halide resins with formaldehyde follows two general courses. The aldehyde may be added to the final resin, mainly as a hardening agent; or the phenol used in the initial reaction may be partially condensed with formaldehyde and subsequently treated with sulphur chloride. McCoy<sup>32</sup> found that the resinous substance formed by the action of sulphur chloride on a phenol in carbon tetrachloride solution is solidified when dissolved in phenol and heated with formaldehyde. Phenol may be mixed with fatty oils and then treated with sulphur chloride and formaldehyde.<sup>33</sup> In a related procedure, the sulphur halide resin is incorporated with formaldehyde, cyclohexylamine and beeswax to prepare a shellac substitute.<sup>34</sup>

Ellis<sup>35</sup> observed that the addition of 3 per cent of paraform, hexamethylenetetramine or formaldehyde was sufficient to raise the softening point of a phenol-sulphur chloride resin about 28°C. and that further amounts conferred no beneficial effects. The compositions containing paraform are lighter in color than those with hexamethylenetetramine. In preparing molding materials, the filler may be impregnated with a resin solution, the solvent removed by evaporation and the product

powdered. To illustrate, a resin (100 parts) derived from "metaparacresol" and sulphur chloride is dissolved in 200 parts of denatured alcohol with 3 parts of stearic acid (serving as a mold lubricant). A solution of 6 parts of hexamethylenetetramine in 100 parts of denatured alcohol is mixed with 100 parts of wood flour and evaporated. The resulting material is incorporated with the resin solution forming a paste that is dried for about 3 hours at 100°C. and powdered for molding. As the formaldehyde does not make the resins infusible but merely raises their softening points, the finished article may be broken up if defective and molded again.

The action of sulphur chloride on phenol-formaldehyde resins has been especially studied by Samuel<sup>36</sup> who was interested in the production of heat- and electrical-insulators. This investigator prepared a partially condensed product from cresol and formaldehyde which was still soluble in alcohol and acetone. To the condensate was then added as much sulphur monochloride as would continue to react. The evolved hydrogen chloride had to be neutralized to prevent further polymerization of the phenol-formaldehyde resin. The final product contained about 12 per cent of sulphur and was soluble in alcohol, acetone, hydrocarbon solvents and pyridine. When heated to 80°C. the resin softened, and at 150°C. it polymerized rapidly to a hard, infusible mass insoluble in all the ordinary solvents. The hardened resin possessed a high dielectric constant, its resistance being given as  $300 \times 10^6$  megohms per centimeter. Samuel named the resin "Thiolite" and used the unpolymerized form in thermosetting molding compositions.<sup>37</sup> Solutions of the partially condensed product have also been used as coating and impregnating agents.<sup>38</sup> The resin is heated, after the solvent evaporates, to convert it into a hard and infusible mass.

#### PHENOL-SULPHUR RESINS

Phenol and sulphur form, under certain conditions, resins having diverse applications as in molding, tanning and in the dyeing industry. In general, though differing in preparation the phenol-sulphur resins closely resemble the phenol-sulphur halide products previously described.

In the initial interaction of sulphur and phenol, o-hydroxybenzenethiol is probably first formed and oxidized by the excess sulphur to o,o'-dihydroxydiphenyl sulphide.<sup>39</sup>

As in the sulphur-halide reaction, the phenol nucleus retains unreplaced hydrogen atoms in the ortho and para positions. Hence, the molecule may branch out on these positions also:

<sup>36</sup> A. A. Samuel, *Compt. rend.*, 1926, 182, 207; *Plastics*, 1927, 3, 13; *Chem. Abs.*, 1926, 20, 2712. *Ind. Eng. Chem., News Ed.*, 1926, 4 (6), 7. U. S. It is possible, moreover, for each of the sulphur linkages to take up more sulphur giving polysulphides of greater complexity than the products of the phenol-sulphur halide reaction.

More complex phenols give analogous reactions with sulphur. Thus, Lefevre and Desgrez<sup>40</sup> obtained 2,4,2'-trihydroxybenzophenone-5,5'-disulphide from 2,4,2'-trihydroxybenzophenone and sulphur. In a similar manner, the disulphides of 2,4,2'-trihydroxybenzosulphone, 3-hydroxy-3'-aminobenzosulphone and 2,2'-dihydroxydiphenylamine can be prepared.

**Preparation of Phenol-Sulphur Resins.** A relatively simple procedure for the preparation of phenol-sulphur resins was developed by Canavan.<sup>41</sup> Tar acids (crude mixture of phenols) are heated in an autoclave with sulphur. Part of the hydrogen sulphide evolved during the reaction is allowed to escape, maintaining a pressure of 50 lbs. per square inch. The most efficient temperature for the process is stated to be 230°C. The resin may be used as a flotation reagent according to Canavan.

The majority of investigators in the phenol-sulphur resin field have employed catalysts (usually bases) to hasten production. Ellis<sup>42</sup> heated 50 parts of phenol with 80 parts of sulphur and 1-10 parts of potassium carbonate for 4 hours at a temperature of 135-140°C. The temperature was then raised to 160°C. for another 4-hour period, resulting in the formation of a hard resin that liquefied slowly at 130-140°C. Higher proportions of sulphur increased the melting point of the product. Since the resin was intended for use in molding compositions, retention of the base employed as catalyst was undesirable, for subsequent decomposition with the liberation of hydrogen sulphide would occur. To remove the carbonate, the pulverized resin was washed or dissolved in alkali and precipitated with acid.

A non-dyeing sulphur-phenol composition, described by Downing, Clarkson and Hannum,<sup>43</sup> was prepared by employing a limited proportion of sulphur insufficient to react with all the phenol. Sodium phenolate is first formed by heating 376 g. of phenol and 40 g. of powdered sodium hydroxide at 180°C. To the molten mass, 160 g. of sulphur are added, and the mixture is heated at 182°C. until the evolution of hydrogen sulphide ceases. Unreacted phenol is removed by steam distillation, and the resin is cooled and powdered. Dissolved in water with the aid of sodium carbonate, the resin gives a greenish-brown solution that confers on cloth great affinity for basic dyes.

Like the phenol-sulphur halide products described earlier in this chapter, the phenol-sulphur resins decrease in solubility as the sulphur content increases. Blumfeldt<sup>44</sup> obtained resins soluble in alcohol, acetone and alkalis by restricting the amount of alkali to less than 0.2 the equivalent of the phenol and using only 2-3 mols of sulphur per mol of phenol. On molding, these resins become hard and insoluble, and they are suggested as substitutes for the more expensive Bakelite types. The phenol-sulphur resins may be hardened by the addition of formaldehyde or hexamethylenetetramine.

Resins, derived from phenol and sulphur, with large proportions of alkali have been used as mordants<sup>45</sup> for dyes and as coloring matters by themselves.<sup>46</sup> One

method for the preparation of mordants employs only 0.6 per cent of sodium hydroxide in a melt of phenol and sulphur, but the resulting mass is cooled, ground with a further 25 per cent of sodium hydroxide and fused before use.<sup>47</sup>

A modification of the general procedure consists in refluxing a solution of phenol in caustic alkali with sulphur.<sup>48</sup> Instead of using sodium or potassium hydroxide, Bergdolt and Ballauf<sup>49</sup> catalyzed the reaction with a solution of an alkali-metal carbonate. Thauss<sup>50</sup> recommends substituting sodium formate for sodium hydroxide as the catalyst.

FIG. 163.

Cupboard in One of the Author's Laboratories. This was varnished with a sulphur-phenol resin composition over 15 years ago. Finish is still in good condition.

Battegay<sup>51</sup> stated that alkali hydroxides tended to give poor yields of phenol-sulphur resins which, furthermore, were lacking in uniformity. This observer suggested that a small amount of iodine be utilized in place of alkali. The initial interaction with iodine as catalyst is reported to form iodophenol which on dissociation facilitates the resin-forming reaction. Compounds of aluminum and antimony together with hydrogen fluoride have also found use in the preparation of resins from phenols and sulphur.<sup>52</sup>

Besides their application in molding and in dyeing cotton, the sulphur-phenol resins have been utilized to protect animal fibers from the action of alkaline

liquids,<sup>65</sup> to diminish the tendency of hydrated cellulose to swell<sup>66</sup> and in the dyeing of rubber.<sup>66</sup>

**Modified Sulphur-Phenol Resins.** During discussion of the phenol-sulphur chloride resins, the preparation of mordants by the addition of tin compounds was noted. Muth<sup>66</sup> similarly treated bodies obtained from phenols and sulphur. Thus, the sulphur-phenol compositions are dissolved in aqueous alkali and heated with stannous chloride, potassium hexachlorostannate or sodium stannate. After heating, the resin-tin complex is isolated by acidifying or by evaporation. Some of the products possessed not only mordanting properties but were found to serve as wool-resists in dyeing mixed fabrics. Wool-reserving substances of the same general nature have been made by fusing sulphur-treated phenol with a phenol and sodium stannate.<sup>67</sup>

Leeman and Kartaschoff<sup>68</sup> prepared related mordanting, tanning and wool-reserving bodies by the action of sulphur on phenol in a water solution of an alkali hydroxide or carbonate together with ammonium molybdate, chromium acetate, tin chloride or aluminum sulphate. The alkali could be replaced by iodine or an alkali salt of a weak acid (e.g., sodium formate, mentioned previously).<sup>69</sup> Materials also proposed as tanning agents were developed by Kraus<sup>70</sup> using sulphur, phenols (especially naphthols), sodium sulphite and formaldehyde. As an example, 144 kg. of  $\beta$ -naphthol, 100 l. of water, 20 kg. of sodium hydroxide and 80 kg. of powdered sulphur are refluxed for 40-80 hours and then diluted with 250 l. of water. On cooling, 250 kg. of crystallized sodium sulphite and 80 kg. of 40 per cent formalin are incorporated with the solution. The final liquid becomes entirely clear after standing for some time at 70-80°C., and subsequent to neutralization is ready for use as a tanning reagent. Schütte<sup>71</sup> varied the procedure by reacting the phenol first with formaldehyde and sodium sulphite and then treating the resulting product with sulphur and alkali. The tanning reagents can be mixed in the dry state with solid acids so that their solutions will have the requisite acidity.<sup>72</sup>

Daimler<sup>73</sup> proposed the reaction of sulphur and alkali with phenolic resins. The products, in the form of alkali salts, are soluble but precipitate on the addition of acids. The material formed by heating an aldehyde-phenol condensate with iodine and sulphur may be employed as a rubber anti-oxidant.<sup>74</sup>

Resins, soluble in alcohol and acetone, produced by the reaction of phenol and sulphur in the presence of limited amounts of alkali were modified by Blumfeldt<sup>75</sup> with acetic anhydride. The resin is heated with the acetylating agent at 150-180°C. until no longer soluble in alcohol. After distilling off excess acetic anhy-

dride and the acetic acid formed in the reaction, the product is a light-yellow to brown powder soluble in acetone, cyclohexane, chloroform and ethylene chloride, but insoluble in alcohol and alkalis. Benzoyl, acetyl or p-toluenesulphonyl chloride may also be employed. The modified resins were said to resemble closely the natural resinotannol<sup>66</sup> esters and hence could be used in lacquers and as impregnants.

**Miscellaneous Sulphur-Phenol Resins.** Cherry<sup>67</sup> prepared resins by combining the action of sulphur and sulphur chloride on phenols. Specifically, 50 parts of sulphur are dissolved in 200 parts of sulphur monochloride and the solution added slowly to 100 parts of phenol. The resulting composition is said to be satisfactory when used in molding. Analogous products in which sulphur is replaced by selenium were also investigated by Cherry. Selenium oxychloride and its reaction with phenols have been studied by Morgan and Burstall.<sup>68</sup> With phenol itself, there are produced initially two isomeric selenonium chlorides of the type  $[(HO-C_6H_4)_2Se] Cl$ . The more soluble of the two is obtained as a gum setting to a glassy mass when kept over sulphuric acid. Cresol gives, in addition to the selenonium chloride derivative, a small amount of bis(4-hydroxy-3-methylphenyl) selenide and gummy by-products. According to Meyer and Wagner,<sup>69</sup> selenic acid when poured on well-cooled phenol and diluted with water gives a light-brown precipitate that cannot be crystallized. In contrast with the reaction of sulphuric acid and phenol, no phenolselenonic acid can be isolated.

Condensation products of formaldehyde and naphthalene sulphonic acids (described in Chapter 12) react with hydroxyaromatic alcohols to give tanning agents and resists used in the dyeing of animal fibers.<sup>70</sup> Resinous substances are obtained by the action of aluminum sulphide<sup>71</sup> and chlorosulphonic acid<sup>72</sup> on phenol at temperatures below the latter's boiling point.

#### AROMATIC AMINES AND SULPHUR CHLORIDE

The mechanism of the action of sulphur halides on aromatic amines differs only slightly from that of phenols and sulphur halides (described earlier in this chapter). Hydrogen chloride splits out, but in some cases at least part of the hydrogen removed comes from the amino group. Herz,<sup>73</sup> employing a considerable excess of sulphur chloride with aniline hydrochloride, prepared a yellow crystalline substance to which the formula

was assigned. Other aromatic amines, their salts and acyl derivatives gave similar products (both in the dry state and in the presence of diluents) serving as dye intermediates. A related material from o-toluidine was proposed by Christmann<sup>74</sup> as a pickling inhibitor.

<sup>66</sup> Acyl derivatives of resin alcohols containing phenolic hydroxyl groups.

Coffey<sup>75</sup> found that with dilute solutions and low temperatures an excess of aniline reacts in the following manner:

The product ( $\text{C}_6\text{H}_5\text{NS}_2$ ) was a thick orange-red oil which Coffey named N-dithiophenylamine. On standing the molecular weight of this compound increased indicating polymerization. The substance may be used as a vulcanizer for rubber, according to Whittelsey and Bradley.<sup>76</sup>

Merz and Schmidt<sup>77</sup> studied the action of several sulphur halides on aniline. With sulphur iodide at 160-170°C., thioaniline (bisaminophenyl sulphide) and a considerable quantity of a dark resinous body assumed to contain dithioaniline (bisaminophenyl disulphide) were obtained. Aniline and sulphur bromide with benzene as a diluent gave a resinous mass from which small quantities of dithioaniline and thioaniline could be extracted with acid. From sulphur chloride and aniline, a resin containing dithioaniline and thioaniline formed.

The preparation of resins by the action of sulphur chloride on primary aromatic amines was investigated by Meigs<sup>78</sup> who noted that higher temperatures tended to produce substances soluble in hydrocarbon solvents and to some extent in alcohol, whereas reaction at lower temperatures generally yielded masses having greater solubility in water. Products ranged from a pasty mass, part of which dissolved in oils and the rest in alcohol, to a resin (prepared with larger proportions of sulphur chloride) 60 per cent of which was insoluble in acids.

A secondary amine (diphenylamine) was treated by Ingram<sup>79</sup> with sulphur dichloride at 10°C. in carbon tetrachloride. The reaction was believed to proceed as follows:

The compound obtained was employed as an anti-oxidant in rubber mixes. Other secondary amines,<sup>80</sup> aniline<sup>81</sup> and amides<sup>82</sup> have been reported as giving a similar reaction with sulphur dichloride. Holzmänn<sup>83</sup> and Kym,<sup>84</sup> however, postulated formulas for the products obtained from diphenylamine and di- $\beta$ -naphthylamine in which hydrogen was removed from the ring. The structure of the compound from diphenylamine was represented by

Considering tertiary amines, apparently the only reaction possible is the removal of nuclear hydrogen, forming such compounds as bis(dimethylaminophenyl) sulphide<sup>85</sup> and disulphide.<sup>86</sup>

phide is liberated and two substances are isolated.<sup>80</sup> One is dehydrothiitoluidine (or p-aminophenyltoluthiazol) and the second is called Primuline.

The latter is a dye and, since it is insoluble, is used in the form of a sulphonated derivative. In all probability the molecule is larger than the formula indicates and is formed by a number of such condensations. Bogert and his co-workers<sup>80</sup> studied the reaction of p-toluidine and sulphur at lower temperatures (140-145°C.) in the presence of litharge. They postulate the initial reaction to be the formation of a mercaptan which is converted by the simultaneous oxidizing action of sulphur and litharge to thio-p-toluidine and a disulphide.

The disulphide formed in this reaction and that obtained from aniline have been found to improve the strength of cured rubber.<sup>81</sup> Resin formation has been reported to result on fusing the pure benzal derivative of o-amino-m-cresol (3-hydroxy-6-benzalaminotoluene) with sulphur.<sup>82</sup>

The previously mentioned researches on amines and sulphur apparently have not had as an objective the preparation of resins for molding or other commercial purposes, although resinous by-products are mentioned several times. Blumfeldt and Kaegi<sup>83</sup> found that brownish resins could be obtained by the action of

sulphur on primary and secondary amines with the exceptions of p-toluidine and N-alkylanilines. A transparent, yellowish-brown resin remains after heating 93 parts of aniline and 96 parts of sulphur, first at 185°C. and then for 21 hours at 250°C. The product softened above 100°C. and became insoluble and infusible when heated for a longer period.

Bly<sup>94</sup> reported that nickel, iodine and tungstic acid accelerated the interaction of sulphur and aniline at the latter's boiling point. Molded products fabricated from these resins were said to be good electrical insulators and to have smooth glossy surfaces. Aside from moldings, such products have been employed in anti-corrosive paints<sup>95</sup> and as binding agents in attaching abrasives to rubber.<sup>96</sup>

As with phenol-sulphur resins, several investigators have studied the modification of sulphur-amine compositions with formaldehyde. Application to the mounting of microscopic objects has been suggested for a condensation product of sulphur, aniline and formaldehyde.<sup>97</sup> Bedford<sup>98</sup> synthesized rubber-vulcanization accelerators by heating sulphur with an amine-formaldehyde condensate. Methylene diphenylamine (N,N'-diphenyl methylenediamine), anhydroformaldehydeaniline<sup>99</sup> and hexamethylenetetramine could be used.

**Miscellaneous Amine-Sulphur Resins.** Carbon disulphide was found by Lommel, Goost and Friedrich<sup>100</sup> to react with secondary alicyclic bases giving products of an oily or resinous nature which could be used in rubber vulcanizing. These were soluble with difficulty in ether or benzene, but some dissolved in chloroform, alcohol or water. For example, 76 parts of carbon disulphide were run gradually into a stirred and cooled mixture of 127 parts of hexahydroethyl-aniline, 99 parts of hexahydroaniline and 400 parts of ice water. The oily product (the hexahydroaniline salt of ethylhexahydrophenyldithiocarbamic acid) crystallized after some time. Carbon disulphide, primary amines (aniline, methyl- or butylamine) and aldehydes (butylaldehyde or acetaldehyde) also condense to form vulcanization accelerators.<sup>101</sup> The ratios of reactants were 2 mols of aldehyde, 1 or 2 mols of amine, and 1 mol of carbon disulphide.

Bigelow<sup>102</sup> studied the reaction taking place between benzalaniline and carbon disulphide in an autoclave at 170°C. The pure products isolated from the resulting tar were phenyl mustard oil, stilbene, thiobenzanilide and tetraphenylthiophene. Claus and Krall<sup>103</sup> found that the carbon disulphide which they used as a diluent for the reaction of sulphur chloride and aniline entered into the composition. The initial products were aniline hydrochloride, sulphur and thiocarbanilide. The last then reacted with the sulphur chloride to give triphenylguanidine and phenyl mustard oil. Carbon disulphide combines, as is well known, with alkali cellulose to form viscose. Harrison<sup>104</sup> reported that, when viscose is dissolved in water with an amine and oxidized, stable products are obtained which can be employed in making films and threads.

On refluxing sulphur with nitrobenzene, sulphur dioxide is given off and the mixture gradually thickens. Depending on the proportion of sulphur and length

of heating, Wilson<sup>106</sup> obtained resins of differing softening points. The mass formed by heating 369 parts of nitrobenzene and 160 parts of sulphur for 5-7 hours was mixed with fillers and cold molded. A stronger resin could be made by adding furfural to the mass before shaping the product. In this case the excess nitrobenzene was driven off first. The same was true of the hot-molding compositions made with higher proportions of sulphur.

A number of other products more or less related to the preceding ones have been reported. Thus, Binapfl and Strohmenger<sup>106</sup> prepared a vat dye by heating at 210°C. a mixture of azobenzene, o-cresol, sulphur and zinc chloride. Ishikawa<sup>107</sup> in studying the reaction of sulphur chloride on thioamides obtained  $\alpha$ -naphthimino- $\alpha$ -isothionaphthamide as a resinous substance. At 200°C., nitrobenzene, o,o'-dithioaniline and litharge react to form a black tar.<sup>108</sup> Matzurevich<sup>109</sup> refluxed aniline with thiosemicarbazide and hydrazinedithiocarboxamide and stated that in every case resinous by-products were formed. Thionylaniline condenses with malonic acid to form a resin.<sup>110</sup> As an anti-oxidant in rubber compositions, Scott<sup>111</sup> used a hard black resin made by heating an acetone- $\alpha$ -naphthil (obtained from acetone and  $\alpha$ -naphthylamine in the presence of iodine) with sulphur.

## Chapter 60

### Various Sulphur-Treated (Vulcanized) Products

Sulphur and sulphur halides react with a great variety of compounds. Aromatic amines, phenols,<sup>1</sup> fatty oils and various hydrocarbons all give sulphurized products. In certain cases, reaction occurs easily on simple mixing of the two reagents. This is true of the action of sulphur chloride on phenols, amines and unsaturated hydrocarbons.<sup>2</sup> However, when sulphur is employed, the temperature usually has to be raised before reaction takes place. Saturated hydrocarbons both of the aromatic and aliphatic series require the presence of a catalyst before any reaction with sulphur chloride starts.

The best-known vulcanizable hydrocarbon is rubber. Although a detailed description of the vulcanization of this substance is beyond the scope of the chapter, there are certain characteristics of hard rubber which relate it to synthetic resins. It is a good dielectric, and when mixed with softening agents and fillers it can be molded. It is also chemically resistant and, therefore, has been used both by itself and as a lining for steel in the manufacture of chemical apparatus. In the latter case, a layer of soft rubber is interposed between the hard rubber and the metal. Such an intervening layer makes the bond between the ebonite and the metal stronger and more elastic.<sup>3</sup> (See Figs. 164 and 165.)

#### REACTION OF SULPHUR COMPOUNDS WITH TERPENES

The primary action of sulphur on terpenes appears to consist in the formation of a monosulphide which then combines with more sulphur to form polysulphides.<sup>4</sup> A resin produced by the sulphurization of turpentine was obtained by Pratt<sup>5</sup> and is known as "Toron." This material was the result of work on a solvent (for reclaimed rubber) in which turpentine was the base. During the experimentation, sulphur was introduced and, on heating, it was observed that sulphur and turpentine formed a black viscous material. The hardness and viscosity of the resulting body depended on the time and temperature of the operation. Long heating at an elevated temperature gave a hard substance similar to mineral rubber. The product was readily soluble in benzene, toluene, xylene, gasoline and other hydrocarbon solvents and was partially soluble in acetone and alcohol. Solutions of Toron were thought to be non-colloidal since they penetrated the fibers of cloth

<sup>1</sup> See Chapter 59.

<sup>2</sup> See Chapter 54 for the discussion of the action of sulphur halides on rubber. In Chapter 10, various products are mentioned which are obtained from the reaction of sulphur and its halides on petroleum distillates. For a further discussion of the latter topic see Carleton Ellis, "Chemistry of Petroleum Derivatives," Chemical Catalog Co., Inc., New York, 1934.

<sup>3</sup> A review on hard rubber has been contributed by A. R. Kemp and R. S. Malon, *Ind. Eng. Chem.*, 1935, 27, 141. See also D. F. Twiss, *Trans. Inst. Rubber Ind.*, 1928, 3, 386; *Chem. <sup>5</sup> W. B. Pratt, U. S. P. 1,349,909, Aug. 17, 1920; *Chem. Abs.*, 1920, 14, 3338. British P. 165,662, 1921. Cf. B. S. Rao, V. P. Shintre and J. L. Simonsen, *J.S.C.I.*, 1928, 47, 171T.

readily. Analyses and molecular-weight determinations indicated that sulphur had added to the olefinic linkages of the terpene and also that several terpene nuclei had been linked together. Since hydrogen sulphide was evolved it would further appear that some substitution had taken place.<sup>6</sup>

Toron is prepared by heating sulphur and turpentine together under a reflux condenser. At 150°C., the reaction progresses readily and the temperature is gradually raised to 200°C. The material can also be formed by digesting the two reactants together at 140°C.<sup>7</sup> The principal use for which Toron was intended was the impregnation of fabrics employed in the manufacture of rubber goods. Solutions of Toron, as was mentioned above, penetrate the fibers and facilitate the formation of a firm bond between the fabric and the rubber.<sup>8</sup> Cloth impregnated with solutions of these sulphur-terpene resins is reported to be waterproof.<sup>9</sup> Not only solutions of Toron but also aqueous emulsions can be used for such purposes.<sup>10</sup>

Gardner and Hart<sup>11</sup> prepared a similar material by heating turpentine and sulphur for about 12 hours at 120-130°C. Their product was used as a rubber accelerator and as an ingredient in a carbon-black pigment.<sup>12</sup>

Kobbe<sup>13</sup> heated 2 parts of pine oil with 1 part of sulphur at 190°C. for about 30 minutes. The resulting composition was then mixed at 120-140°C. with 25 parts of lubricating oil and the mixture employed as a cutting oil.<sup>14</sup> The reaction of various sulphurizing agents (sulphur, alkali sulphides and nitrogen sulphide) on pinene is stated by Budnikov<sup>15</sup> to produce a terpene sulphide of the formula,  $C_{10}H_{16}S$ . With gold chloride this sulphide formed a compound which could be used in gilding porcelain. Gray<sup>16</sup> thickened turpentine with sulphur chloride and utilized the product for bonding rubber to metal. Another material, an ingredient for rubber compositions, was obtained by blowing pine-tar oil with air at an elevated temperature and in the presence of a small proportion of sulphur.<sup>17</sup> Lubs, Fox and Smith<sup>18</sup> report that the action of sulphur chloride (75 g.) on pine oil (100 g.) at below room temperature (cooled with ice and then, after mixing, allowed to warm up to room temperature) followed by refluxing with alcoholic sodium sulphide (285 g. in 1000 cc.) produced an effective flotation agent. Other hydrocarbons and certain of their derivatives were also mentioned as forming similar products. Benzene and dichlorobenzene required catalysts before the reaction would take place. Aluminum chloride and aluminum amalgam were used for this purpose.

A number of varnishes have been made by heating sulphur with solutions of rubber. Such varnishes were used for impregnating fabrics to make them water-

proof and electrically insulating.<sup>19</sup> As a solvent in this reaction, Pratt<sup>20</sup> employed turpentine which had previously been treated with oxalic acid. He states that the product was not a colloidal solution since it would pass through parchment. Another vulcanized terpene-rubber combination has been prepared by Gray<sup>21</sup> through heating 50 parts of pine oil, 100 parts of rubber, 80 parts of sulphur, 40 parts of clay and 2 parts of accelerator at 149°C. for 1 hour. When this composition was pulverized, it could be remolded at 177°C. in 2-5 minutes.

#### ACTION OF SULPHUR AND SULPHUR HALIDES ON AROMATIC HYDROCARBONS

The reaction of sulphur on benzene in the presence of a catalyst has been studied by Glass and Reid<sup>22</sup> and by Dougherty and Hammond.<sup>23</sup> The former investigators heated benzene and sulphur together in a bomb at 350°C. for 24 hours. The products isolated were thiophenol, diphenyl sulphide, diphenyl disulphide, thianthrene and hydrogen sulphide.

thianthrene

Dougherty and Hammond used aluminum chloride as catalyst and were able to isolate only thianthrene, diphenyl sulphide<sup>24</sup> and hydrogen sulphide. The mechanism suggested was:

Others have obtained thianthrene from benzene and sulphur chloride in the presence of metallic chlorides.<sup>25</sup> If the reaction is made to go further by using more sulphur chloride and by increasing the time and temperature, resinous substances are produced. Although the composition of these bodies is not known it is possible that they are in the form of chains containing sulphur-linkages similar to those present in thianthrene and diphenyl disulphide. Stegemann<sup>26</sup> observed that heating sulphur (1 per cent) with crude benzene at 250°C. for 2 hours formed a small amount of pitch, a reaction which Uloth<sup>27</sup> applied to the purification of benzene. Apparently the unsaturated compounds present in the crude distillate are the first to react and so are removed.

<sup>27</sup> R. Uloth, *Brennstoff-Chem.* 1929, 10, 297; *Brit. Chem. Abs.* B, 1929, 767. F. Hofmann and R. Uloth, British P. 306,421, 1929; *Chem. Zentr.*, 1929, 2, 963.

Hassler<sup>28</sup> obtained tanning agents<sup>29</sup> and varnishes<sup>30</sup> by fusing naphthalene,<sup>31</sup> sulphuric acid and sulphur together at 160-180°C. In place of the naphthalene and sulphuric acid a naphthalenesulphonic acid<sup>32</sup> could be used. The products were bluish-black before neutralization of the acid, but afterwards they were yellowish brown. Some of these resins were water-soluble whereas those produced using more sulphur and less sulphuric acid were insoluble. Experiments in the author's laboratory have given more information as to these relationships. When the following proportions were employed the product was soluble in water and fusible:

Naphthalene . . . . .	50 parts
Sulphur . . . . .	15
Sulphuric acid . . . . .	125

Raising the sulphur to 24 parts and reducing the sulphuric acid to 60 yielded a material only part of which was water-soluble. The water-insoluble portion could be mixed with filler and hot molded to give an article having a hard glossy surface. Raising the sulphur to 36 parts resulted in an insoluble and infusible black solid.

Delaney and Richardson<sup>33</sup> heated equal parts of naphthalene and sulphur monochloride together in the presence of a catalyst, e.g., tin, aluminum or ferrous sulphides, and obtained a resin suggested for use in making phonograph records. The temperature was held at around 95°C. at which point the reaction goes rather rapidly. The product on hot molding became substantially insoluble and infusible. Cherry<sup>34</sup> reported that wear-resistant phonograph records can be made of a composition containing naphthalene-sulphur resin, ozokerite and an appropriate filler.

Anthracene and sulphur chloride yield 9-anthryl dithiochloride, ( $C_{14}H_9S_2Cl$ ), a yellowish-red crystalline compound melting at 117-118°C. and reacting with ammonia and aromatic bases to form resinous bodies.<sup>35</sup> It has also been observed that sodium disulphide reacts with dibromoanthracene, when heated in an autoclave, to form a yellow, insoluble and amorphous compound.<sup>36</sup> Frey<sup>37</sup> reported that anthracene (25 per cent) and sulphur (2.5 per cent) heated with coal-tar pitch resulted in a product similar in chemical and physical properties to the original pitch. Further, the sulphurized products made by heating cuprene<sup>38</sup> with benzene and sulphur or sulphur chloride have been stated to be of use in the rubber industry.<sup>39</sup>

A chemically resistant material has been obtained by Balle and Daimler<sup>40</sup> by incorporating a sulphurized aromatic hydrocarbon resin with a fusible phenol-formaldehyde condensation product. Thus, 400 parts of technical xylol were

<sup>28</sup> F. Hassler, U. S. P. 1,533,594, April 14, 1925; *Chem. Abs.*, 1925, 19, 1791. German P 407,994, 1918, and 409,713, 1920; *J.S.C.I.*, 1925, 44, 517B, 642B. German P 406,269, 1926, *Chem. Abs.*, 1929, 23, 2257.

<sup>29</sup> Using sulphur chloride in a similar reaction between naphthalene and sulphuric acid, a resist for use in dyeing animal fibers has been obtained (Faibw vom Meister, Lucius & Bruning, British P 248,007, 1926, to I. G. Farbenind. A.-G.; *Brit. Chem. Abs.*, 1927, 628). See Chapter 59 for some other resists made from sulphur chloride and phenols.

<sup>30</sup> Sulphuric acid is reported as being a catalyst for the preparation of varnishes from naphthalene and sulphur chloride (A. Ya. Savitzkii and P. G. Novak, Russian P. 33,299, 1933; *Chem. Abs.*, 1934, 28, 3605).

<sup>31</sup> The material known as "Hyrax" and which is used in mounting microscopic objects is said to be a naphthalene resin (G. D. Hanna, *J. Roy. Microscopical Soc.*, 1931, 50, 424; *Chem. Abs.*, 1931, 25, 1858).

<sup>32</sup> J. L. Heid (*J.A.C.S.*, 1927, 49, 844) has reported that tars are obtained by heating naphthalene-2,7-disulphonic acid at 180°C.

reacted with 500 parts of sulphur monochloride and 8 parts of zinc chloride. One hundred parts of the resulting resin were fused with 30-50 parts of a condensation product from cresol and formaldehyde. The mixture was a black mass possessing a high melting point.

#### VULCANIZED BITUMINOUS MATERIALS

Numerous investigators have suggested that useful materials can be prepared by the action of sulphur or sulphur chloride on bituminous substances. Since in most, if not all, of these cases the initial substance is a complex mixture, very little can be said about the structures of the resulting products. However, the principal reaction is probably with any unsaturates present, since Lorand<sup>41</sup> has shown that it is the olefinic constituents of petroleum distillates which interact primarily with sulphur chloride. The saturated hydrocarbons were found to react much more slowly giving chlorinated (not sulphurized) materials. Two suggested applications for the bodies obtained by treating tar oils with sulphur and sulphur chloride are the preparation of black printing colors<sup>42</sup> and ingredients for paints.<sup>43</sup> Hessele<sup>44</sup> obtained sulphurized products by heating a hydrocarbon oil with sulphur in the presence of catalysts such as the oxides and hydroxides of chromium, manganese, iron, cobalt and nickel. Hessele also stated that resinous and heavy polymerized masses resulted when the metallic catalyst was omitted.

Kurath<sup>45</sup> described the use of stearin pitch in a cold-molding composition prepared by melting together 1050 parts of stearin pitch, 945 parts of coal-tar pitch and 105 parts of gilsonite at 260°C. The mixture was cooled to 246°C. and 168 parts of fish oil were added. An emulsion of 40 parts of this binder and 9 parts of sulphur in 6 parts of water was then added to 150 parts of asbestos. The resulting mass was disintegrated and molded. Pungs<sup>46</sup> heated stearin pitch with sulphur, wood oil, whale oil and an extract of tar and obtained an adhesive and impregnating composition to be used in treating textiles. A related body formed by vulcanizing a mixture of linseed oil and stearin pitch has been employed as an insulating compound.<sup>47</sup>

Asphalt and similar bituminous materials have been heated with sulphur to make a vulcanized impregnant for stone,<sup>48</sup> a briquet binder<sup>49</sup> and a product for use in road-making.<sup>50</sup> Bolgar<sup>51</sup> heated asphalt and sulphuric acid together until the mixture was homogeneous, allowed the mass to cool and then stirred in sand. In this way he obtained a plastic composition. Sulphonation of sulphurized coal-tar is said to produce a tanning agent.<sup>52</sup>

As was noted previously, benzene is relatively inert to sulphur. An anti-corrosive paint has been prepared by mixing in a benzene vehicle asphalt, rubber and gum elemi, followed by heating with sulphur, sulphur chloride or arsenic sulphide.<sup>53</sup>

perfections with a vulcanized composition of rubber, castor oil and sulphurized asphalt.<sup>63</sup> Vulcanized rubber dissolved in a mixture of water-gas tar and coke-oven tar and heated with sulphur gave a product which could be used in electrical insulation and in road building.<sup>64</sup>

Reif<sup>65</sup> developed a procedure for making plastic compositions from fibrous materials and sulphurized tars. The loose fibers were saturated with ammonia or dusted with a powdered base (calcium hydroxide or sodium carbonate) and then sprayed with tar. Each fiber was thus coated with a thin layer which was then vulcanized by a spray of sulphur chloride. The hydrogen chloride liberated from the reaction was neutralized by the base present. The final product could be molded when hot.

## SULPHURIZATION OF NATURAL AND SYNTHETIC RESINS

When rosin, abietic acid, abietene or abietane is heated with sulphur and then distilled, retene is obtained.<sup>66</sup> Under milder treatment than distillation, less thorough changes in the molecule take place and various sulphurized bodies have been obtained. Thus, Moltke-Huitfeldt<sup>67</sup> heated rosin (500 g.) and sulphur (125 g.) for 1 hour at 155-160°C. The powdered mass after cooling was dissolved in sodium carbonate solution at 100°C. A transparent, yellow, gelatinous soap was obtained. Valenta<sup>68</sup> added sulphur to melted rosin and secured a black product closely resembling Syrian asphalt in properties. It did not dissolve in alcohol but was soluble in benzene and chloroform. On evaporation, a benzene solution left a solid film which became insoluble when exposed to light.

Rosin and a number of other natural resins are too soft to make good varnishes.<sup>69</sup> Low<sup>70</sup> reports that they can be hardened by heating under pressure with an aqueous suspension of sulphur. Prager<sup>71</sup> states that the addition of 5-10 per cent of sulphur at 140-150°C. produces a dark green, stable material. Various non-metallic inorganic sulphur compounds (sulphur chloride, chlorosulphonic acid, sulphuric acid and thionyl chloride) have been used also to modify rosin.<sup>72</sup>

Nielsen<sup>73</sup> heated 50 parts of rosin with 25 parts of mineral oil ("medium" automobile oil) to 102°C. A thin stream of melted sulphur (at 123°C.) was poured in with agitation. When cold, 10 parts of rice flour were incorporated and the product was suggested as a mastic composition in laying wood blocks. An artificial gutta-percha has been prepared by Zingler<sup>74</sup> from a mixture of copal, sulphur flowers and petroleum or turpentine. After cooling, the mass was mixed with an ammoniacal solution of casein and heated to 126-150°C. until it had the consistency of a thin fluid. It was then boiled with 15-25 per cent of tannic acid and finally washed with water and dried.

Ohta<sup>75</sup> made an electrical insulating varnish by heating tung oil and rosin with sodium sulphide or selenide. Aluminum was used as a catalyst and the temperature was held between 240° and 300°C. Selenium (0.1 per cent) added to a mixture of a drying oil and a natural resin is said to prevent the mixture from burning during the heating required to produce a varnish.<sup>76</sup> Papier-mâché or wood has been impregnated with a composition made from resin, lime, boiled linseed oil and sulphur. This product, according to Faure,<sup>77</sup> is acid-proof and applicable for making storage batteries. A fiberboard has been made by coagulating a suspension of fibers, sulphur and rosin size with alum followed by forming into sheets.<sup>78</sup>

Urushiol is one of the principal constituents of the juice obtained from the Japanese varnish tree, *Rhus vernicifera*.<sup>79</sup> This juice (Japanese lacquer) is poisonous to the skin but, according to Satow,<sup>80</sup> is rendered nonpoisonous when

heated with 40-60 parts of sulphur at 120-160°C. The product was converted by treatment with formaldehyde or acetaldehyde to a rapidly hardening material, which could be mixed with fillers and molded or used as an impregnating or coating agent when dissolved in benzene, benzene or acetone. The coatings were insulators for electricity. They could also be utilized as glues in veneering. A similar protective layer has been made by pasting a sheet of asbestos paper to a surface, followed by painting with vulcanized urushiol and heating to 150-200°C. This layer was said to be resistant to hydrochloric and other acids.<sup>81</sup> A mixture of vulcanized Japanese lacquer, hard rubber and a polymerized mixture of a drying oil and manganese or cobalt resinate have also provided an electrical insulation.<sup>82</sup>

Venugopalan<sup>83</sup> studied the effect of sulphur and sulphur chloride on shellac. He reports that the mechanical properties and water resistance of the varnishes and molded products made from vulcanized shellac were both improved. Treatment with sulphur was carried out by heating the shellac with 3-4 per cent of sulphur at 180°C. until the product after cooling was green in color. When sulphur chloride is added in chloroform solution to a varnish made of shellac, it is stated that not only is the water resistance increased, but also the color is improved. These changes, according to Aldis,<sup>84</sup> are due to the hydrochloric acid liberated.

Resin-like substances have been obtained by treating salts of resinic, humic or lignoceric acids with chlorides of aromatic sulphonic acids.<sup>85</sup> For example, 100 kg. of  $\alpha$ - or  $\beta$ -naphthalenesulphonyl chloride were added to a solution of 120 kg. of sodium colophionate in 100-200 kg. of water. The solution was heated at 30°C. for 12 hours and then allowed to cool. The precipitate formed (separated by decantation or filtration) was then dissolved in benzene for the purpose of purification. The organic acid salts could be replaced by soft coal-tar pitch or anthracene-oil distillates. The products were used as varnishes.

A number of synthetic resins<sup>86</sup> have been vulcanized. Arsem<sup>87</sup> heated the reaction product of glycerol, phthalic anhydride and oleic acid with 10-30 per cent of sulphur. The product was an elastic rubber-like material. Ellis<sup>88</sup> treated solutions of alkyd resins with sulphur chloride. He found that a restricted amount of the halide (1-2 per cent) was desirable since otherwise the product was darker in color. For example, a resin was prepared from 80 parts of phthalic anhydride, 50 parts of glycerol and 40 parts of distilled cottonseed fatty acids. One thousand parts of this resin were then dissolved in 1500 parts of a mixture of benzene and ethyl acetate (equal parts). To the solution were added 10 parts of sulphur monochloride, the mixture stirred thoroughly and allowed to stand for 2 hours. Magnesium oxide (5 parts) was incorporated to neutralize the acid and the solution was filtered. Such a resin solution gave coatings which were less tacky than those formed using the unvulcanized alkyd. On heating, the films became substantially infusible and insoluble. Nitrocellulose could be added to these compositions. Resins to be used in varnishes have also been obtained by Ott, Steinmeyer and Frick<sup>89</sup>

by vulcanizing alkyd resins (modified by drying oil acids) with less than 5 per cent of sulphur.

According to Herrmann and Haehnel,<sup>90</sup> polyvinyl alcohol and its derivatives give products resembling rubber when treated with sulphur or sulphur chloride. Thus, they heated polyvinyl alcohol at 150°C. for 5 hours with 1 per cent of sulphur. The resulting material was black, hard and rubber-like. It could be worked by cutting or sawing. The use of a 10 per cent solution of sulphur monochloride in carbon disulphide produced a plastic material resembling soft rubber.

Lender<sup>91</sup> states that coatings of polymerized cumarone and indene become fissured and brittle in time. This he reports is largely prevented if the resin is heated with sulphur or sulphur chloride before using it in a varnish. It has already been noted that the insolubility of phenol-formaldehyde resins in the final stage of condensation hindered their application to oil varnishes.<sup>92</sup> In one of the methods for avoiding this difficulty, a fusible phenolic resin is vulcanized at 332°C. with sulphur or with a sulphurized organic compound (turpentine or chlorinated biphenyl). Tung-oil solutions of the product can be bodied by heating to 315°C. without formation of insoluble complexes.<sup>93</sup>

#### VULCANIZED FATTY OILS AS COATINGS

The vulcanization of drying and non-drying fatty oils produces, first, viscous liquid compositions and, second, solid rubber-like bodies.<sup>94</sup> The former are used as coatings and it should be noted that the films from the treated oils are more waterproof and do not penetrate various porous materials. Also, the vulcanized drying oils are said to permit of a more rapid application of successive coats, a property which will be considered more fully later in the chapter in connection with the Frenkel process.

According to Whitby and Chataway,<sup>95</sup> linseed oil reacts with sulphur in three successive steps. The sulphur first combines chemically with the oil. This reaction is relatively rapid, 45 minutes at 160°C. being required for the combination of up to 16.5 per cent of sulphur. Following this, an acetone-insoluble polymer begins to accumulate. This substance is richer in sulphur than the remaining liquid. The mass becomes progressively more viscous and eventually sets to a gel. Concentrated sulphuric acid converts the thick acetone-insoluble oil instantly to a solid polymer, and a similar result is obtained by continuing the heating after the oil has set or by using a larger proportion of sulphur.

The material formed by the action of sulphur chloride on blown linseed oil has been employed by Frenkel and Brust<sup>96</sup> to replace the colloiddally dispersed glass, kaolin or diatomaceous earth commonly used in priming coats. Thus, 30 parts of blown linseed oil were treated with 1-2 parts of sulphur chloride and 40 parts of linseed oil were added before the reaction was complete. Driers were then incorporated and the consistency was adjusted by thinning with ben-

zene.<sup>97</sup> A somewhat similar product has been prepared by Branscombe and Everleigh.<sup>98</sup>

Coatings produced by sulphurized oils are relatively impervious. Hollander<sup>99</sup> found that the sulphur treatment of linseed oil reduced its swelling tendency to a degree comparable with that of stand oil, and under certain conditions the water resistance of tung oil was reached. Rydberg<sup>100</sup> made leather impervious to water by soaking it in a drying oil and then treating with sulphur monochloride. The material obtained by the action of sulphur chloride on tung oil has been proposed by Atkins<sup>101</sup> as a protective coating to render concrete resistant to oil, water, and weather influences. Balloons have also been varnished with a preparation of oils and sulphur chloride.<sup>102</sup> Brandenberger and Riedemann<sup>103</sup> reported that a solution of an oil sulphurized with sulphur chloride was useful in making paints for ship bottoms. Further, this coating was stated to be a good rust preventive. However, Brendel<sup>104</sup> has disputed this, saying that such varnishes may even be corrosive due to the residual hydrochloric acid which they contain.

FIG. 165.  
Tank Lined with Hard Rubber.

Courtesy American Hard Rubber Company

Osnos and Golovistikov<sup>105</sup> studied the reaction of sulphur monochloride and linseed oil in the attempt to prepare varnishes involving the use of smaller quantities of halide. They found that the oxidized oil permitted the desired decrease in the amount of reagent and that the resulting varnish was better than those containing 14-16 per cent of sulphur monochloride. Heublyum<sup>106</sup> reviewed their work and also came to the conclusion that the amount of sulphur chloride should be kept as low as possible. Others who have investigated the use of sulphur- and sulphur chloride-treated oils have reported that a sulphur-treated tung oil has not only an increased alkali resistance, but also an increased tendency to blister on plaster.<sup>107</sup> The latter property is probably due to its impermeability to moisture. Sulphur chloride-treated linseed oil, on the other hand, did not show increased alkali resistance.

<sup>97</sup> O. Naumann (German P. 597,209, 1934; *Chem. Abs.*, 1934, 28, 5261) suggests the addition of magnesium oleate to factice oil which is intended as a paint vehicle.

Besides being used in the preparation of resistant coatings, sulphurized oils are also said to permit of more rapid application of successive coats.<sup>108</sup> The products from the reaction of sulphur chloride on drying oils set throughout the mass and do not depend on the diffusion of oxygen from the surface. Several layers can be applied in quick succession, i.e., three coats in the course of one day or less. The addition of sulphur to drying oils has also been reported to decrease the destruction of their films by atmospheric oxidation.<sup>109</sup> Related to this is the process of Beringer and Zimmer<sup>110</sup> who prevent the congealing of tung oil during heat treatment by the addition of 0.6-1.2 per cent of sulphur or selenium. Even though only a small amount of sulphur is used, heating at 250-300°C. produces a light yellow, nondrying, viscous liquid.

Perry<sup>111</sup> found that films made from sulphur chloride-treated fish oils were unsatisfactory. The unsaturated hydrocarbon squalene,  $C_{30}H_{50}$ , which is one of the constituents of shark-liver oil has also been shown to be not suited for use in paints and, in any event, vulcanization does not improve it.<sup>112</sup> Synthetic drying oils have been prepared by dehydrating crude tall oil<sup>113</sup> with calcined calcium sulphate followed by treating with 5-10 per cent of sulphur monochloride<sup>114</sup> and by esterifying sorbitol with oleic acid.<sup>115</sup> In the latter instance, polymerization of the oil can be effected by heating with sulphur.

Various uses of vulcanized drying oils other than for the preparation of paints and varnishes for the protection of wood, plaster and metal have also been proposed. Thus, Nanfeldt<sup>116</sup> impregnated a brake lining containing asbestos with a sulphur-treated linseed oil. Rubber footwear covered with a soft, tacky, vulcanized varnish have been given a hard finish by treatment with a sulphur halide, sulphuryl chloride or thionyl chloride.<sup>117</sup> Fritz<sup>118</sup> prepared a coating composition for the manufacture of oilcloth by dissolving 4-8 parts of sulphur monochloride in 15 parts of benzine, adding slowly 100 parts of bodied linseed oil followed immediately by 20-30 parts of stand oil. The product was used in linseed- or tung-oil solution.

As early as 1864, Parkes<sup>119</sup> reported that castor oil treated with 2-10 per cent of sulphur chloride could be used as a plasticizer for nitrocellulose. Crane<sup>120</sup> heated cottonseed, olive and castor oils with sulphur (0.11-0.20 of the weight of the oil) at 210°C. The syrupy product was employed in nitrocellulose lacquers. The following formula was stated to give good results as a coating for fabrics and leather:

Butyl acetate . . . . .	7 gallons
Petroleum naphtha . . . . .	3 gallons
Pyroxylin . . . . .	15 pounds
Vulcanized oil . . . . .	30-40 pounds
Pigment . . . . .	1-2 pounds

The addition of ammonia to nitrocellulose lacquers lowers the viscosity but yields a brittle film. According to Morozov,<sup>121</sup> this brittleness can be partially eliminated if vulcanized oils are used (in admixture with low viscosity nitrocellulose).

Auer and his co-workers<sup>122</sup> have employed sulphurized resins, oils and naphthenic acids in aqueous emulsion as varnishes and impregnating agents. A similar product has been obtained by emulsifying linseed oil and heating at 160-170°C. with colloidal sulphur.<sup>123</sup> The addition of tannic acid to the oil before or after vulcanizing is said to make the sulphurized body more easily emulsified.<sup>124</sup> Guerrey<sup>125</sup> treated a solution of a salt of an unsaturated fatty acid with a solution of sulphur in carbon disulphide and obtained substances which he assumed to have the typical atomic grouping

Aqueous solutions of these products possessed the property of dissolving animal and vegetable fats, oils, waxes and aromatic hydrocarbons. They were used in degumming silk and for leather dressings.

Not only sulphur and sulphur chloride, but also sulphur dioxide, has been employed in the preparation of varnishes and lacquers from drying oils.<sup>126</sup> For example, oxidized drying oils such as linoxyn or oxidized tung oil are treated with sulphur dioxide, or salts derived from it. The products are soluble in water but may be rendered insoluble by heating.

#### FACTICE

One of the principal uses to which vulcanized oils have been put is the preparation of rubber substitutes. Those made from sulphur monochloride are white to yellow in color and are, therefore, called "white factice." They are formed by mixing the two components in the cold. As reaction is rather violent and the mass tends to heat up spontaneously, it is usually carried out with limited quantities of material lest charring take place. At the end of the reaction the hot mass is poured out on a smooth plate from which it can be easily peeled when cold.<sup>127</sup> Since both sulphur and chlorine are found in the product, Henriques<sup>128</sup> presumed that the white factices were addition products of the oils and sulphur chloride. Considerably larger proportions of sulphur chloride are used in making factice

<sup>126</sup> French P. 738,075, 1932, to I. G. Farbenind. A.-G.; *Chem. Abs.*, 1933, 27, 1773. The products of this reaction can be used also in making inoleum.

<sup>127</sup> T. Seeligmann, G. L. Torrilhon and H. Falconnet, "Indiarubber and Gutta Percha," trans. by J. S. McIntosh; Scott, Greenwood and Son, London, 1910, 261.

<sup>128</sup> R. Henriques, *Chem.-Ztg.*, 1893, 17, 634; *J.S.C.I.*, 1894, 13, 47. The proportions of sulphur and chlorine are not identical with those in sulphur chloride since some hydrogen chloride is lost in the reaction. See E. A. Harvey and H. A. Schuette, *Trans. Wisconsin Acad. Sci.*, 1931, 26, 225, 231, 233; *Chem. Abs.*, 1931, 25, 4726.

than are employed in the case of vulcanized varnishes. Thus, Henriques states that the following amounts of sulphur monochloride give satisfactory results with 100 parts of each of the oils listed:

TABLE 64a.—*Proportions of Sulphur Chloride used with Various Oils.*

Oils 100 Parts	Sulphur Chloride Parts Used
Linseed . . . . .	30
Poppyseed . . . . .	35
Colza <sup>120</sup> . . . . .	25
Cottonseed . . . . .	45
Olive . . . . .	25
Castor . . . . .	20

He points out that there is no relationship between the drying power of the oil and the amount of halide required. Similar observations have been made by Harvey and Schuette.<sup>120</sup> These investigators attempted to develop a method of evaluating oils by treatment with sulphur chloride but found that both the viscosity of the final product and the heat of the reaction were unrelated to the drying power.

The action of sulphur on fatty oils is much slower than that of its chloride. The mixture must be heated before combination takes place. The use of sulphur therefore avoids the accidents which sometimes take place due to the violent action of chloride. The products are dark brown to black in color and are used like the white factices as rubber substitutes and as ingredients in rubber compositions.<sup>121</sup> The preparation of a brown substitute from maize (corn) oil takes place in the following manner:<sup>122</sup> Maize oil (5 parts) is heated to 243°C. and held there for 30 minutes with constant stirring. Melted sulphur (2 parts) is then poured in and when the mass is thoroughly mixed it is run out into a cooling box where it may be stirred.

Knight and Stamberger<sup>123</sup> have studied the interaction of sulphur and triolein. They believed that the course of the reaction was very similar to that observed by Whitby and Chataway<sup>124</sup> in the case of linseed oil. The first product was the result of the simple addition of sulphur and was soluble in acetone. Then the sulphurized molecules condensed with more sulphur to produce an insoluble elastic body. The sulphurized oleic acids formed on hydrolysis were not elastic.

As indicated above, one of the uses to which such products have been applied is the compounding of rubber.<sup>125</sup> Dittmar<sup>126</sup> added soya-bean oil to rubber solutions which were to be vulcanized with sulphur monochloride. The sulphur halide reacted with the oil to form a factice *in situ*. The elongation and suppleness of the vulcanizate was increased. There was, however, a tendency to age poorly and compositions containing more than 20 per cent of oil became worthless in a few

<sup>120</sup> R. Girard and J. Legoute (French P. 700,867, 1929; *Chem. Abs.*, 1931, 25, 3876) used lead tetroxide as a catalyst in the preparation of rubber substitutes from colza oil and sulphur chlorides.

<sup>120</sup> E. A. Harvey and H. A. Schuette, *Ind. Eng. Chem. Anal. Ed.*, 1930, 2, 42; *Ind. Eng. Chem.*, 1931, 23, 675. *Trans. Wisconsin Acad. Sci.*, 1931, 26, 225, 231, 233; *Chem. Abs.*, 1931, 25, 4726.

<sup>121</sup> R. Henriques (*loc. cit.*) bases his analysis of rubber compositions for white and brown factice on the fact that the latter contains sulphur but no chlorine. For the analysis and examination of factice see Grandel and Co., *Kautschuk* 1931, 7, 48; *Chem. Abs.*, 1931, 25, 4441.

<sup>125</sup> See W. Alexander (*Kautschuk*, 1924, 10, 18; *Chem. Abs.*, 1924, 28, 4628) for a review of the preparation and use in rubber of white and brown factices.

<sup>126</sup> R. Dittmar, *Gummi-Ztg.*, 1926, 41, 535; *Chem. Abs.*, 1927, 21, 671. H. A. Gardner (U. S. P. 1,446,039, Feb. 20, 1923; *Chem. Abs.*, 1923, 17, 1560) vulcanized a mixture of rubber, benzene and dechlorinated oil with sulphur. (See Chapter 56.)

months. Another way of incorporating the factice is to add it in the form of an emulsion to an aqueous dispersion of rubber.<sup>137</sup>

Some other uses for factice have been suggested. One of these is the preparation of linoleum. A mixture of factice, quartz and the product of sulphur dichloride on linseed oil was recommended for this purpose.<sup>138</sup> Kaufmann<sup>139</sup> replaced the linoxyn ordinarily employed in the manufacture of linoleum with factice, and the customary resin with a synthetic one resulting from the action of sulphur monochloride on naphthalene. It has even been suggested that factice can be used as the intermediate layer in safety glass.<sup>140</sup> Snelling<sup>141</sup> mixed cottonseed oil, carbon disulphide and sulphur chloride and poured the solution on a metallic surface where it was left until hard. The mass was then ground and sulphur chloride mixed with a small quantity of methyl alcohol was added. Liquefaction occurred and the liquid was stirred into an excess of water. A solid separated and this was milled with an equal weight of rosin and the mixture boiled 3 hours in water. The product was used as a gutta-percha substitute. An insecticide has been prepared by heating dichlorobenzene with a vulcanizable oil and sulphur chloride until the mixture sets to a hard mass which is powdered.<sup>142</sup> McCoy<sup>143</sup> considered that factice was a desirable addition to phenol-formaldehyde condensation products. The resulting resins were mixed with plasticizers and fillers and then molded.

A large number of the fatty oils can be used in the preparation of these rubber-like products. Several such substances have already been named. To this list should be added sandal-seed oil<sup>144</sup> and various modified oils. De Waele<sup>145</sup> produced elastic masses by vulcanizing acetylated castor oil or acetylated blown oil with sulphur chloride, sulphur thiocyanate or dithiocyanogen. Hagedorn<sup>146</sup> reports that the moldable material formed by heating the mixed ester of cellulose and phenylacetic, oleic and lauric acids with sulphur at 140°C. is resistant to acids, alkalis and atmospheric oxygen.

Mineral oils are not usually considered vulcanizable. However, Snelling<sup>147</sup> found that rubber-like bodies could be produced from them. He added 20 cc. of methyl alcohol and 50 cc. of carbon disulphide to 100 g. of lubricating oil. One hundred cc. of sulphur chloride were added and the mixture allowed to stand 5 days in a sealed container. The methyl alcohol accelerated the reaction so that at the end of this time a considerable change had taken place in the oil. The liquid was then thoroughly mixed with 500 cc. of water and left in contact with it for 6 days. The excess water and oil were removed by running the resulting mass through rolls. A solid product resulted which was tough and elastic. Oleic acid when treated similarly produced a substitute for lanolin.

<sup>147</sup> W. O. Snelling, U. S. P. 1,535,740, April 28, 1925; *Chem. Abs.*, 1925, 19, 1968.

Nüth<sup>148</sup> prepared factice by the action of sulphur dichloride<sup>149</sup> on solutions of various oils in benzene and toluene. When heated with an amine, the factice slowly mixes, with the evolution of hydrogen chloride. Thus, samples of factice were prepared using the proportions shown in Table 65.

TABLE 65.—*Factice Preparations.*

Series	Oil		Sulphur Dichloride
A	Linseed	10 parts	3
B	China wood	10	3
C	Poppyseed	10	4
D	Castor	75	6
E	Cod liver	4	1

The resulting bodies were heated at 125-140°C. with the proportions of amines given in Table 66.

TABLE 66.—*Amine-Factice Compositions.*

Factice		Amine	
Linseed	A 1 part	Aniline	3 parts
Linseed	A 1	p-Chloraniline	1
Linseed	A 10	m-Nitraniline	7
China wood	B 1	p-Toluidine	1
China wood	B 1	Monoethyl p-toluidine	4
China wood	B 1	Dimethyl aniline	2
Castor	D 1	Aniline	5
Cod liver	E 1	Aniline	4

When the factice was in solution, a quantity of toluene was added and the amine-hydrochloride precipitate was filtered off. The toluene solution could be used directly as a varnish, or the reaction product could be separated and purified by precipitation and washing with alcohol. If harder materials were desired than those prepared as just described, the latter could be vulcanized by heating with sulphur.

Linseed, cottonseed, castor and other oils react with zinc oxide or hydrated lime when heated to 200°C. to form a product which is hard, but porous and disintegrated by water. Barringer<sup>150</sup> found that the addition of sulphur yields an impervious mass which is not attacked by water. One composition which he used consisted of 20 parts of zinc oxide, 8 parts of sulphur, 40 parts of ground flint, 12 parts of powdered talc, 20 parts of asbestos and 15-20 parts of linseed oil. After thorough mixing, the composition was fashioned into the desired shapes and baked for 4-8 hours at a temperature ranging from 150 to 220°C. Saponification and vulcanization were best carried out at 200-220°C. Although articles made by Barringer's process had a slightly grayish tone instead of the bluish black preferred by molders, they were resistant to water and could be soaked in the latter for weeks with no apparent deterioration.

An earlier composition which consisted of lime, boiled linseed oil, resin and sulphur has previously been mentioned.<sup>151</sup> Ievlev<sup>152</sup> also described the production of plastic bodies. Wood pulp was ground with a drying oil and powdered chalk. Separately, a lime-sulphur was prepared by adding sulphur to lime during the

<sup>148</sup> G. Nüth, U. S. P. 1,159,257 and 1,159,258, Nov. 2, 1915; *Chem. Abs.*, 1916, 10, 296

<sup>149</sup> H. Plauson and J. A. Vielle (British P. 156,143 and 156,144, 1920, *Chem. Abs.*, 1921, 15, 1831, 1832) have vulcanized a factice prepared using sulphur dichloride and obtained an artificial ebonite. The same type of factice was combined by N. Braibant (British P. 374,656, 1922; *Chem. Abs.*, 1923, 27, 3795) with rubber and an abrasive to form a honing composition.

course of hydration. The two intermediate compositions were mixed and treated with a solution of sodium silicate.

Auer's preparation of varnishes from the action of sulphur and sulphur halides on oils and resins has been mentioned previously. He has also made plastic bodies<sup>108</sup> by similar methods. For example, castor oil was boiled under reduced pressure with metallic calcium until the latter was dissolved and the evolution of hydrogen had ceased. After cooling, the reaction mass was heated to 140°C., mixed with iron oxide, aniline and sulphur, and further heated to 160°C. This product could be molded under pressure.

## Chapter 61

# Resin-Like Materials from Fatty Oils and Miscellaneous Vegetable Oils

Although the polymerization products of the fatty oils are not resins and do not compare in importance with many of the types of resinous products which have been discussed in previous chapters, nevertheless they do comprise a group containing a very wide variety of materials with a correspondingly broad field of applications. No consideration will be afforded here to the numerous compositions which contain heat-treated oils in mere admixture, for the discussion will be confined to those products which fall somewhat vaguely within the category of synthetic resins. The drying and semi-drying oils<sup>1</sup> are notably polymerizable, especially under the influence of catalysts. Chlorination of various fats and oils yields rubber-like polymers, and insulating compositions result from the polymerization of castor oil. A novel and very interesting development has been the introduction of the use of cashew-shell oil for the preparation of resinous materials.

### TUNG OR CHINA WOOD OIL

Reference<sup>2</sup> has already been made to the employment of tung oil (China wood oil) with rosin, ester gums and other like materials. Substances resulting from the utilization of tung oil itself are now to be discussed.

The gelatinization of tung oil on strong heating is a familiar change, the chemistry of which has been investigated to some extent. Marcusson<sup>3</sup> studied the nature of the coagulation phenomenon, and, from solubility tests of heated tung oil, concluded that gelatinized oil contains 3 constituents besides oxidation products and anhydrides: (1) unchanged oil, (2) an oily polymerization product and (3) a solid polymerization product, the amounts of each varying according to the conditions of heating.<sup>4</sup>

Tung oil contains chiefly the glyceride of eleostearic acid with a small proportion of oleic and stearic glycerides.<sup>5</sup> The first of these acids is triply unsaturated, and is responsible for the characteristic properties of the oil. The polymerization of tung oil is assumed<sup>6</sup> to involve the eleostearic radical. The more highly polymerized molecules are less soluble in acetone, and consequently the matter insoluble in acetone increases rapidly with the temperature of heating. Accordingly, tung oil treated at relatively low temperature has greater ease of flow, can be thinned out to a larger extent, and produces a more elastic film. In contrast with

<sup>1</sup> For further information regarding the chemistry of film formation of drying and semi-drying oils, particularly linseed oil, see J. S. Long, A. E. Rheineck and G. L. Ball, *Ind. Eng. Chem.*, 1933, 25, 1086. G. W. Ellis, *J.S.C.I.*, 1925, 44, 401T. F. Ohi, *Farbe u. Lack*, 1934, 554; *Chem. Abs.*, 1935, 29, 945.

<sup>3</sup> J. Marcusson, *Z. deut. Oel.-Fett-Ind.*, 1923, 43, 162; *Chem. Abs.*, 1923, 17, 2198.

<sup>4</sup> The difference in refractive indices of tung oil and its unpolymerisable fraction, being a constant, is the basis of a test for adulterants (vegetable tallow, rape or poppy-seed oil and rosin). F. Cheng, *Trans. Sci. Soc. China*, 1934, 8, 97; *Science (China)*, 1934, 18, 758; *Chem. Abs.*, 1935, 29, 362.

<sup>5</sup> For a discussion of the characteristic acids of drying oils see J. Bössekens, *Chem. Weekblad*, 1934, 31, 418; *Chem. Abs.*, 1935, 29, 2002.

<sup>6</sup> L. A. Jordan, *J.S.C.I.*, 1934, 53, 1T.

this, oil treated at a higher temperature does not have such good brushing qualities, but the film, when prepared, is more durable.

Tung oil contains 80-85 per cent of  $\alpha$ -eleostearic glyceride, and this is completely converted into the  $\beta$ -isomer in the presence of catalysts. Each form can be readily isolated.<sup>7</sup> It has been stated that stand oils made from  $\alpha$ -tung oil do not differ perceptibly from those from the  $\beta$ -oil.<sup>8</sup> Maleic anhydride adds to the conjugated unsaturation of each isomer but, according to Morrell, Marks and Samuels,<sup>9</sup> only the addition product with  $\beta$ -eleostearin produces films which can be hardened by heat. Thus, in this instance, the thermal-hardening property is taken to be related to the stereo-isomeric structure. Rossmann<sup>10</sup> believed that a cyclization phenomenon accompanies tung oil polymerization, and the product is a mixture of monomeric and dimeric 5-butyl-1,3-cyclohexadien-6-caprylic acid.

Köhler<sup>11</sup> has studied the cooking of tung oil at 280° and 320°C. The product obtained at 280°C. was the more satisfactory for use with resins in lacquers. The less viscous oils, prepared at lower temperatures, are best used, according to Köhler, with linseed stand oil. Friction blocks may be made by saturating asbestos pulp or woven fabric with an oil binder such as tung oil and subjecting the product to heat and pressure.<sup>12</sup>

Condensation products are formed when tung oil is treated with phenols in the presence of sulphuric acid.<sup>13</sup> Baekeland<sup>14</sup> devised a process whereby tung oil is heated at 205-210°C., without solidification, mixed with a filler (wood flour, asbestos or silic), and the mixture molded and baked. The molded articles are given a coat of asphalt or phenolic condensation products. Electrical insulators may be made in this manner. Tung oil can also be polymerized in the presence of hydrocarbon oils.<sup>15</sup>

For the production of satisfactory varnishes it is often desirable that the gelatinization be retarded, and this is accomplished by the addition of various substances. Rhodes and Potts<sup>16</sup> found the following order of efficacy in this respect: glycerol, oleic acid, rosin, ester gum, cumarone resin and linseed oil. The presence of only 6 per cent of glycerol prevented gelatinization of the oil. This mixture with the addition of lead linoleate, heated to 280°C. until sufficiently bodied and then thinned with turpentine gave rapid drying, smooth, tough, transparent films. The addition of rosin, naphthenic acids or linseed oil to tung oil to avoid its coagulation during heating does not, according to Marcussen,<sup>17</sup> stop polymerization, but merely hinders gel formation. The gelatinization of tung oil may be delayed by heating it with glycerol to a point short of gelatinization and cooling by adding cold rosin oil. The composition is made quick-baking by the addition of a metal soap, such as manganese linoleate, or of a polymerized but ungelatinized resin glyceride, which may be produced by heating a mixture of glycerol and a resin (Congo copal) with rosin oil. The composition after application to a metallic article is hardened by the action of heat, which

drives off the rosin oil from the polymerized material.<sup>18</sup> The addition of thymol and  $\beta$ -naphthol to tung and linseed oil was found by Hilpert and Niehaus<sup>19</sup> to retard polymerization.

When exposed to ultraviolet light or treated with small quantities of iodine, sulphur chloride, sulphur or ozone, tung oil changes to a solid, the  $\beta$ -form. The latter can be heated at 260°C. to secure a gasoline- or naphtha-soluble resin adaptable for varnishes.<sup>20</sup>

Bürstenbinder<sup>21</sup> considered that the action of the majority of the retarding substances is purely mechanical. The effect of sulphur on the heated oil is, however, an exception. Even as little as 0.01 per cent of sulphur has a decided retarding action on the drying of the oil.

Gardner<sup>22</sup> reduced the iodine number of tung oil, and hence its tendency to dry rapidly with the formation of brittle, "frosted" films, by heating to 290°C. with a small amount of sulphur (0.05 per cent) or an organic sulphur compound. Addition of a heavy metal or metal oxide (lead, copper or zinc) effects desulphurization of the oil when hot, leaving a product of less unsaturation than the original substance but with improved coating properties. Selenium is reported to be related to sulphur in its action.

When tung oil is heated very rapidly, as can be accomplished by passing it through a heated coil, it may be brought to a temperature exceeding 300°C. without gelatinization taking place, and such "thermolyzed" oil is used commercially as a constituent of varnishes and nitrocellulose lacquers.<sup>23</sup>

Thauss and Mauthe<sup>24</sup> found that tung oil and phenol react in the presence of dilute sulphuric acid, and that on treating the product with concentrated sulphuric acid (which acted as a sulphonating agent), a resinous substance was formed soluble in alkalis and suitable for treating textile materials. The oil may also be heated with 2-naphthol-6-sulphonic acid and dilute sulphuric, to yield a thick condensation product.<sup>25</sup> Marcusson found that treatment of tung oil with nitric or sulphuric acid causes polymerization to a solid substance. Linseed and other fatty oils give no separation of solid with nitric acid, and the reaction is therefore adapted for distinguishing tung from other oils.<sup>26</sup> A similar test with a drop of sulphuric acid (concentrated) serves to detect 10 per cent or more of tung oil in raw, boiled or blown linseed oil.<sup>27</sup> A thickening oil for lacquers is made by heating tung oil to 300°C. with acetic acid and nitrosodiphenylamine in the absence of oxygen.<sup>28</sup> The use of tung oil in aqueous colloidal solution has been suggested.<sup>29</sup>

Hydrogenated tung oil was used by Seigle<sup>30</sup> to impregnate asbestos brake shoes or linings, which were later exposed to a temperature at which polymerization of the oil occurs. Tung oil, hydrogenated until its iodine number has fallen to 120-130, is used with or without the addition of a small percentage of gilsonite

for impregnation, the temperature of the impregnated material being raised to 240°C. to effect polymerization.

#### TUNG OIL AND METALLIC CHLORIDES

Scobel<sup>21</sup> made use of the reaction between tung oil and anhydrous chlorides. On grinding anhydrous ferric chloride or its hydrates with the oil, a solid is produced which is non-coherent, yellow in color, and which gradually darkens. When the ferric chloride is ground in an indifferent oil (such as rosin oil or linseed oil) and then quickly mixed with tung oil, a homogeneous mass is formed. If allowed to solidify in molds, these products retain the shape of the container. The solidification is accompanied by a perceptible increase of temperature and volume. The molded articles are very glossy and jet black in appearance. They are opaque except when in thin sections. When first removed from the mold or container, the solid substance is slightly tacky, but soon loses this property on exposure to the atmosphere, or when kept at a temperature of 90-100°C. for a few hours. Prolonged exposure to elevated temperatures has a hardening effect on the mass. The outer portions, which are in contact with the atmosphere, become very much firmer than the interior. With zinc chloride the solid products are brown to deep red and sometimes they are translucent. Aluminum chloride gives a very deep brown to black color.

In the polymerization of tung oil by metallic chlorides, rosin and ester gum or other oil-soluble resins<sup>22</sup> can be employed up to 40 per cent by weight of the tung oil used. When quantities in excess of 40 per cent are employed the product is deficient in resiliency, is quite brittle and softens at somewhat above room temperature.

Tung oil fatty acids can be solidified by active chlorides in anhydrous solvents, but preferably in conjunction with the raw or blown oil itself. Specimens of oil which have been partially polymerized are unsuitable because products solidified from these oils soften and grow sticky at comparatively low temperatures. Tung oil which has been heated above the polymerization point with small amounts of sulphur can be solidified in the usual manner.

One kilogram of tung oil alone requires 25 cc. of a 20 per cent solution of ferric chloride in anhydrous acetone to cause solidification. As much as 150 cc. can be used on that quantity of oil to make a firmer product.<sup>23</sup> Tung oil containing rosin or ester gum requires somewhat larger amounts of ferric chloride in solution. Usually most additions such as rosin, wood flour, cork and other fillers and pigments exercise a retarding influence on solidification, and it is found desirable to use larger amounts of ferric chloride solution or stronger solutions in such compositions.

A formula suggested for making slabs for tile or flooring is: 8 kg. of tung oil and 2 kg. of rosin are dissolved by warming and ground with 1½ kg. each of infusorial earth, wood or cork flour and oxide of iron (red), to which is added 1 kg. of a solution of ferric chloride in acetone (made from equal parts by weight of hydrated ferric chloride and anhydrous acetone). Another formula is: 1 kg. of tung oil containing 40 per cent rosin, 0.5 kg. of tung oil containing 10 per cent ester gum, 50 g. cork meal, 50 g. wood flour, 100 g. Indian red, 200 g. magnesium silicate or other mineral filler and 100 cc. of a solution made from 1 kg. of ferric chloride and 1/3 kg. of anhydrous acetone.

<sup>21</sup> B. Scobel, U. S. P. 1,833,864, July 5, 1921; *Chem. Abs.*, 1921, 15, 3758.

<sup>22</sup> E. Lichtenstern (U. S. P. 1,720,487, July 9, 1929; *Chem. Abs.*, 1929, 23, 4321) found that on heating asphalt (containing not more than 10 per cent of a condensing agent such as ferric chloride, zinc chloride or aluminum chloride) to 270-280°C. and mixing with a quantity of tung oil not exceeding that of the asphalt used, an infusible mass is formed on further heating which may be used on roads, floors or for treating pasteboard.

<sup>23</sup> Twenty cubic centimeters of a saturated solution of ferric chloride in ether when stirred into 1 gallon of raw tung oil will cause it to gel in 30 minutes. *Circ., Am. Paint Varnish Mfrs. Assoc.*, 1929, 342, 66, 66.

Stannic chloride (anhydrous) in cooled anhydrous acetone also produces an active solidifying solution. The pure fuming anhydrous chlorides of tin or antimony cannot be used without such a solvent, for their action on the oil is too energetic, causing clotting or non-uniform solidification.

According to Marcusson,<sup>54</sup> anhydrous stannic chloride is a catalyst for the polymerization of tung, linseed and fish-liver oils. The polymerized fatty acids from tung oil could be separated into (1) solid acids (acid value 186, saponification value 199.5, iodine value 81), yielding sodium salts soluble in water but insoluble in alcohol, and (2) pale, unimolecular, semi-liquid acids soluble in light petroleum ether and forming sodium salts soluble in alcohol. Oleic acid treated with aluminum chloride in the cold is also converted into a solid mass, slightly elastic when broken.<sup>55</sup>

Tung oil, and other unsaturated oils, may be made water-soluble by treating their oxyns with sulphur dioxide and alkali. Such water solutions yield resinous products upon treatment with inorganic chlorides.<sup>56</sup> It has been suggested that inorganic halides catalyze rearrangement of the double bonds in unsaturated glycerides.<sup>57</sup> Polymerization of tung oil occurs in the presence of zinc chloride and acetone peroxide.<sup>58</sup> Adulterants delay the time required for catalytic solidification.<sup>59</sup>

#### TUNG OIL AND AROMATIC AMINES

Lilienfeld<sup>40</sup> has made resinous compositions by heating tung oil with toluidine and a condensing agent. A hardening effect may be obtained by treatment with formaldehyde. A product of a resinous nature is obtained by heating one kg. each of o-toluidine and tung oil with 150-200 g. of zinc chloride in 60-100 g. water. The temperature is maintained between 200° and 300°C. until a satisfactory degree of resinification is reached. When employing formaldehyde the following procedure is recommended: 1 kg. tung oil mixed with 1 or 2 kg. of o-toluidine is heated to 80°C. and 110 g. of zinc chloride dissolved in an equal weight of water added. The temperature is slowly raised while agitating the mixture and the excess of toluidine which distils is collected. The temperature of the heating bath is gradually raised to 260-290°C. and is maintained in this neighborhood until the mass becomes hard and resin-like on cooling. The resinified material is washed by kneading with water and is heated gradually with 20-200 g. of aqueous formaldehyde or an equivalent amount of trioxymethylene. A modification of the process involves adding the formaldehyde with the toluidine.

Auer<sup>41</sup> found that resins were formed when linseed, tung, or castor oils were heated above 200°C. with primary aromatic diamines. These products were suggested for use as varnishes. By the incorporation of an alkali, followed by vulcanization, rubber substitutes are formed. Resins are also prepared by condensing tung oil with polynuclear methylenic compounds of aromatic amines.<sup>42</sup> Solvents and condensing agents could be employed and hardening attained by aldehyde treatment. For example, a thick oil was formed from tung oil, aniline

and aniline hydrochloride. This was heated with anhydroformaldehydeaniline for 1-2 hours at 200°C., then treated with formaldehyde.

Tests have been carried out in the author's laboratory on the production of resins from tung oil, and aniline, p-toluidine or xylidene. Thus, 50 parts of oil and 50 parts of aniline were placed in a round bottom flask with 10 parts of zinc chloride dissolved in 5 parts of water. The flask was connected with a condenser and gradually heated. Vigorous frothing occurred between 100° and 120°C. and a small amount of water was distilled out. On further heating to 200°C. the liquid boiled quietly and was of a light yellow color. A slight quantity of oily substance was distilled off during this period. At 210°C., a second frothing took place and the substance began to darken, while water and a small amount of oil distilled. At 280°C., the substance was still liquid and could be easily poured out of the flask. On cooling it gave a reddish-brown resin, but on further heating, the mass solidified inside the flask forming a spongy, sticky, resinous body, less fusible than the resin obtained from the solution heated only to 280°C. The yield of resin amounted to 70 per cent of the total weight of material taken. The product obtained at 280°C. is of good transparency and brittle, but slightly tough, when cold. It does not harden even on heating for several hours. Some of its properties, together with those of similar resins from p-toluidine and xylidene, are shown in Table 67.

TABLE 67.—*Properties of Tung Oil-Amine Resins.*

Properties	Aniline	Resin from Tung Oil and p-Toluidine	Xylidene
Melting point . . . . .	115-120°C.	65-70°C.	41-43°C.
Test on hot plate . . . . .	Gummy	Tarry	Thick liquid
Heating with 20% of paraform	Hardened in 3 minutes	Gummy in 4 hours	No effect
Solubilities			
Alcohol . . . . .	Insoluble	Soluble warm	Soluble
Benzene . . . . .	Insoluble	Slightly soluble warm	Partly soluble
Acetone . . . . .	Slightly soluble warm	Soluble	Soluble
Ether . . . . .	Insoluble	Insoluble	Difficultly soluble
Alcohol-Benzene . . . . .	Partly soluble warm	Soluble warm	Easily soluble
Alcohol-Acetone . . . . .	Partly soluble warm	Soluble warm	Soluble

#### CHLORINATED OILS AND FATS

A general procedure for preparing resin substitutes by exhaustive chlorination of various organic substances, proposed by Boehringer,<sup>44</sup> involves dissolving the substance (an oil, fat, wax or rosin) in carbon tetrachloride and treating the solution with chlorine gas. An increase in temperature accompanies the first stage of chlorination, but later a drop in temperature occurs. Chlorination is continued far beyond this point, exposure to actinic light serving to reduce the time required for the reaction. Chlorinated paraffin and ceresin wax show a notable resistance to the action of strong acids.<sup>44</sup> Colorless oils or sticky, plastic solids, useful as dyeing assistants, are formed in the chlorination or bromination of fatty acids (above C<sub>8</sub>).<sup>45</sup> The free halogen or a mixture of chlorate and hydrochloric acid may be employed. Ricinoleic acid gives products containing 3, 6, 7 or 16 atoms of chlorine; oleic acid takes up 3 or 4; stearic acid, 6; and dihydroxystearic acid, 5 atoms of chlorine. Treatment of these chlorinated derivatives with strong alkalis yields alkali-soluble products, proposed as cleansing and emulsifying agents. On boiling with sodium hydroxide, rubber-like polymers are obtained.<sup>46</sup>

<sup>44</sup> German P. 256,856, 1910 and 258,156, 1911, to C. F. Boehringer & Söhne; *J.S.C.I.*, 1913, 32, 499, 613.

<sup>45</sup> For particulars of the chlorination of waxes and oils see Chapter 56.

<sup>46</sup> British P. 336,623, 1929, to I. G. Farbenind. A.-G.; *Brit. Chem. Abs.* B, 1931, 149.

<sup>46</sup> British P. 340,011, 1929, to I. G. Farbenind. A.-G.; *Chem. Abs.*, 1931, 25, 2737. See also British P. 342,761, 1929; *Brit. Chem. Abs.* B, 1931, 450.

When tung oil is treated with chlorine until the reaction has somewhat abated and the temperature begins to fall, a body containing about 28 per cent of chlorine is obtained. This product is a thick, dark liquid and splits off hydrochloric acid continuously on standing at room temperature.<sup>47</sup> Further chlorination in carbon tetrachloride solution yields a solid, transparent substance.<sup>48</sup>

The drying power of tung or soya-bean oil is improved by mixing the oil with about 20 per cent dry calcium hypochlorite and heating at 60-70°C.<sup>49</sup> Another procedure which may be used is to heat the drying oil (tung, etc.) with a chlorine-containing organic compound or with a so-called "dechlorinated mineral oil." Thus, fatty oils were heated with chlorinated fats or with p-toluene sulphonyl chloride and were converted into products of the stand-oil type.<sup>50</sup> Gardner<sup>51</sup> has found that "dechlorinated oils" (mineral oil, chlorinated, and then treated for the elimination of chlorine) facilitate the gelatinization of tung oil. The product is extremely resistant to most chemical reagents.

### CASTOR OIL.—ESTOLIDE FORMATION

Castor oil,<sup>52</sup> as is well known, consists essentially of the glyceryl ester of ricinoleic acid.<sup>53</sup> Hydrolysis of the oil yields ricinoleic acid of the structure

By the hydrogenation of castor oil 12-hydroxystearin is formed. Hydrolytic cleavage of this stearin does not set free the simple 12-hydroxystearic acid but, rather, these molecules re-esterify intermolecularly. The carboxyl group of one molecule condenses with a hydroxyl group of another and the reaction leads to the formation of compounds of higher molecular weight.

<sup>47</sup> C. F. Boehringer & Sohne, *loc. cit.*

<sup>48</sup> Linseed oil behaves in the same manner. Cotton oil is more heavily chlorinated by exposure to light during the process. See also French P. 433,415, 1911, and 459,261, 1912; *J.S.C.I.*, 1912, 31, 290A; 1913, 32, 1120A.

<sup>24</sup> See also Chapter 43.

<sup>55</sup> According to A. Heiduschka and G. Kirsten (*Pharm. Zentralhalle*, 1930, 71, 81; *Chem. Abs.*, 1930, 24, 1933) the other acids are oleic,  $\alpha$ -linoleic, stearic and dihydroxytearic. See also E. Eibner and E. Münzing, *Chem. Umschau*, 1925, 32, 166; *Chem. Abs.*, 1925, 19, 3027.

These long ester chains are termed *estolides* and may in turn be re-esterified with glycerol yielding polyester fatty acid glycerides of very high molecular weight; complexes of 12,000 and over have been prepared. These are viscous at room temperature, salve-like in the cold and liquid at elevated temperatures.<sup>54</sup> They have valuable technical properties as lubricants and as flexibilizing agents in the textile and leather industry.<sup>55</sup> Saturation of the oil, as by hydrogenation, is not essential to the formation of estolides.

Dihydroxystearic acid according to Bauer and Eberle<sup>56</sup> condenses at 200°C. to an estolide which, from its acid number, must represent at least a 5-fold condensate. At 300°C. the estolide breaks down again into dihydroxystearic acid and ketostearic acid; the latter is formed by ketolization of the 10-hydroxyoleic acid (10-hydroxy-9-octadecenoic-1-acid). By the action of zinc chloride on oleic acid in acetic acid solution, iso-oleic (10-octadecenoic acid) and dihydroxystearic acid were obtained. The latter could be distilled in a vacuum but at 200°C. reverted to an estolide.<sup>57</sup>

Estolides derived from saturated hydroxy acids, and their esters with mono- or polyhydric alcohols find application for oiling artificial fibers of cellulose derivatives.<sup>58</sup> By treating cellulose, or cellulose derivatives containing at least one reactive hydroxyl group with the chloride of an estolidic acid, and a fatty acid chloride, there result products resembling cork.<sup>59</sup> Thus, cellulose, lauryl chloride, chlorobenzene, polyricinyl chloride and pyridine are heated at 125-130°C. for 90 minutes. The product can be molded under pressure when hot.

Wittka<sup>60</sup> found that by heating ricinoleic acid to 180°C. in the presence of naphthene-sulphonic acid with addition of castor oil until saturation is reached, a thick viscous oil is obtained which is the glycerol ester of polyricinoleic acid.

Estolide formation probably underlies the production of lubricants by heating castor oil to 200°C., and introducing glycerol under pressure<sup>61</sup> and the preparation of esters of high viscosity from castor oil by the method of Del-Turco.<sup>62</sup> Castor oil is partially hydrolyzed until the acid number is 80-120, and the washed acid heated to 250°C. in vacuum, with or without a catalyst, to effect auto-condensation. Raw castor oil is then added to reduce the acid number below 6, yielding a product soluble in mineral oils.

The mutual solubility of castor oil and gasoline is found to vary considerably with the composition of the latter. Olefinic, aromatic or naphthenic hydrocarbons are miscible in all proportions whereas the solubility of the paraffins is limited.<sup>63</sup> By heating castor oil with higher fatty acids *in vacuo* (to 230°C. with oleic or to 220°C. with stearic), oils are produced which are soluble in petroleum hydrocarbons.<sup>64</sup> Estolides, in conjunction with drying and semi-drying oils, may be used to prepare sizing for textiles.<sup>65</sup> Castor oil may also be heated with hydrocarbon derivatives whose boiling point is near the polymerization temperature so that they distil off during the process.<sup>66</sup>

The polymerization of castor oil in the presence of metallic oxides yields a composition for coating wire which, according to Harris,<sup>67</sup> can be solidified in contact with the wire by heating to about 300°C. for 3 minutes or less. Copper, ferric or aluminum oxide or alkaline earth oxides are heated with castor oil at 240-310°C. until 5-15 per cent of the castor oil has distilled. Metallic resins and fossil resins also may be employed.<sup>68</sup> Boiled castor oil has found use as a protective coating for metals.<sup>69</sup> A composition that remains flexible comprises oxidized and polymerized castor oil, 60, aluminum oxide, 5, mica, 15, and asbestos 15 parts. The temperature should be above 150°C. during the incorporation of aluminum oxide.<sup>70</sup> Castor oil is rendered more viscous, as well as soluble in mineral oils, by heating with tin oxide at 200-250°C. for 8-12 hours.<sup>71</sup>

Substances resembling tung oil are obtained by heating castor oil at 270-280°C. while it is stirred in air, toluene sulphonyl chloride being employed as a catalyst. The products may be used for making lacquer.<sup>72</sup> Also, the oil may be heated at 200-250°C. in the presence of a substance which retards thickening (rosin, synthetic resin, sulphur, etc.) until the acid number reaches 30 or less. The liquid now somewhat resembles tung oil, and is useful in the manufacture of paints.<sup>73</sup> Heated at 200-260°C. with a small amount of phosphoric acid or of an organic phosphate, castor oil becomes soluble in mineral oil, and on prolonged treatment acquires drying properties resembling those of linseed and tung oil. It may be used as a lubricant or in paints.<sup>74</sup>

Castor oil heated at 100°C. for 1 to 3 hours with concentrated selenious acid yields a rubber-like mass which is insoluble in alcohol, ether, benzene and pyridine. This material is saponifiable with alcoholic potash. When treated with alcohol or ether it swells to a jelly which dries to a solid that can be pulverized.<sup>75</sup> Polymerization can also be accomplished by means of nitric acid: if castor oil at 47.5°C. is treated with 1/80 of its weight of concentrated nitric acid, and the temperature is raised to 116°C., solidification occurs.<sup>76</sup> Nitrated castor oil has been used with nitrocellulose under the trade name of "Velvrl." Such mixtures are homogeneous in all proportions and have been used as artificial rubber.<sup>77</sup> Similar products have been proposed as constituents of explosives.<sup>78</sup> A binding material has been prepared by Cadoret<sup>79</sup> from saponified oils by oxidation with nitric acid and subsequent further saponification. The soap is acidified and the liberated resinoid substance is purified. Cadoret named the product "resoline." In general, drying oils give a vigorous reaction with nitric acid, and semi- or non-drying oils do not. Castor and cedar-nut oils are exceptions to this generalization.<sup>80</sup> With fish oil considerable heat is evolved, but the reaction is not especially violent.

Substitutes for India rubber have been made by heating a solution of amber resin in castor oil with sulphur at 180°C., then cooling the mass and ozonizing.

After this the product was treated with sulphur chloride in the presence of benzene and calcium carbonate.<sup>51</sup>

Under the influence of heat, light or proper catalysts (boric acid, stannic chloride or piperidine) ricinoleic acid was found to condense with itself to form diricinoleic acid.<sup>52</sup> This is a thick, yellowish oil, soluble in alcohol, ether, benzene and acetic acid, and reacts with sulphuric acid to yield an unsaturated ester.

#### DISTILLATION OF CASTOR OIL AND DERIVATIVES

Panyutin,<sup>53</sup> in distilling the methyl ester of ricinoleic acid over pumice and borax (in order to prevent polymerization) found that a cleavage in the molecule took place. Heptaldehyde and the methyl ester of undecylic acid ( $\text{CH}_3(\text{CH}_2)_9\text{COOCH}_3$ ) were obtained. No evidence was available for the shifting of the double bond preliminary to the rupture.

Distillation of castor oil in a vacuum or in a stream of inert gas also yields cleavage products, viz., heptaldehyde and undecylenic acid ( $\text{CH}_2=\text{CH}(\text{CH}_2)_9\text{COOH}$ ). The residue is an oil which may be used to make baking lacquers for metals when mixed with unsaturated acids (oleic) together with metal oxides or soaps and plasticizers (benzyl citrate or phthalate). Inasmuch as copper articles are directly oxidized under these conditions, the metal oxide in this instance is omitted.<sup>54</sup> The free acids of castor oil, however, behave differently in that a cleavage does not take place at the carbon containing the hydroxyl group.

According to Heiduschka and Kirsten<sup>55</sup> the distillation of ricinoleic acid yields a product (b.p. 233-4°C. at 14 mm.) which has a percentage composition indicative of the formula  $\text{C}_{18}\text{H}_{32}\text{O}_8$  but which is a mixture and not a single compound.

When the distillation of ricinoleic or elaidoricinoleic acid is carried out in a vacuum, 70-80 per cent distils over as octadecadienoic acid. By combining the distillate and the residue and esterifying with glycerol, Scheiber<sup>56</sup> obtained a product similar to boiled wood oil.

Esterification of the distillation residues of ricinoleic acid with polyhydroxy alcohols has been used by Scheiber for the preparation of lacs<sup>57</sup> wherein oils and resins are also incorporated. They may be used as vehicles for odorless printing inks<sup>58</sup> in which cellulose esters or ethers are added.<sup>59</sup>

The spongy residue left on distillation of castor oil has been found by Barbot<sup>60</sup> to contain a variety of fatty acids. Esterification with ethyl alcohol gave the heptoate, nonate, undecoate, palmitate, ricinoleate, oleate, stearate and 74 per cent of an unknown acid of molecular weight approximately 700, which appears to be formed from the auto-condensation of linoleic acid.

Böeseken and Hoevers<sup>61</sup> investigated the dehydration product of ricinoleic acid by forming adducts of maleic anhydride<sup>62</sup> and determined that 75 per cent was linoleic acid and 15 per cent 9,12-octadecadienoic-1-acid.

## CONVERSION OF NON-DRYING TO DRYING OILS

Scheiber<sup>96</sup> has classified the fatty oils into (1) those containing conjugated double bonds (tung oil) and (2) those containing several double bonds, non-conjugated (linseed and semi-drying oils). Inasmuch as drying is partially the result of the polymerization of the double bonds, tung oil requires but little outside influence. With other oils it is first necessary to oxidize the methylene group between the two double bonds

before a conjugated system results. By shifting the double bonds of the semi-drying oils, however, compounds are obtained which resemble tung oil in drying properties.<sup>97</sup> By treating the fatty oils of the linseed, poppy seed and train oil types at 200°C. with air or carbon dioxide, this shift in the double bonds takes place and a product similar to tung oil is obtained.<sup>98</sup> Other catalysts include sulphuric acid, antimony pentachloride, aluminum oxide and mercuric oxide.<sup>99</sup>

Linseed oil may also be isomerized to yield a system of conjugated double bonds by treatment with chlorine until the chlorine content is about 20-25 per cent and then dehalogenated with a metal. A clear liquid results which may be used for paint.<sup>97</sup> Gardner<sup>98</sup> has applied this same method to obtain a drying oil from soyabean oil glyceride. Addition of 0.03 per cent of cobalt in the form of a drier to dehydrated ricinoleic acid glycerol ester yields a clear film in 3 to 4 hours.<sup>99</sup>

Synthetic drying oils are also formed by heating castor oil with glycerol and subsequent esterification with unsaturated fat or resin acids.<sup>100</sup> Hydroxylated fats may be prepared artificially by chlorinating fish oils and hydrolyzing the resulting products.<sup>101</sup>

The dehydration product of castor oil obtained by vacuum and chemical dehydration may be heated with excess glycerol to form the glyceryl ester of 9,11-octadecadienoic-1-acid. The films of linseed, and tung oil<sup>102</sup> and the triglyceride of 9,11-octadecadienoic-1-acid, containing cobalt and lead-manganese driers, did not yellow within two years in a desiccator but did so within a few months in ordinary air. The coloration is ascribed to oxidation promoted by water as a carrier. The subsequent bleaching in strong light appears to be a reduction process.<sup>103</sup>

## POLYMERIZED PRODUCTS FROM OTHER FATTY OILS

The first stage<sup>104</sup> in the hardening of a film of linseed oil or similar unsaturated fatty oil in the presence of air is the absorption of oxygen by the fatty acid mole-

<sup>96</sup> J. Scheiber, *Farbe u. Lack*, 1930, 51, 63; *Chem. Abs.*, 1930, 24, 2314. For the classification of fatty oils on the basis of drying properties see the International Critical Tables, McGraw-Hill Book Co., Inc., New York, 1927, II, 201.

<sup>104</sup> J. S. Long, A. E. Rheineck and G. L. Ball, Jr., *Ind. Eng. Chem.*, 1933, 25, 1086.

cule in sufficient quantity to provide one peroxide grouping for each ethylenic linkage. When the molecules have grown to a certain degree of complexity or polarity, they associate and form a solid gel. Further oxidation now becomes unimportant, as the polar liquid phase gradually undergoes transition into a solid phase of substantially the same ultimate analysis. Small amounts of ozone accelerate the rate at which these changes occur.<sup>106</sup>

In the preparation of stand oils from linseed and perilla oils, it was found that the gelatinization was a result of the gradual increase in the proportion of polymerized molecules. These are soluble in the remainder of the oil to a limited extent, and when this limit is exceeded they separate in the form of a gel, and cause the whole mass to set.<sup>106</sup> Similarly, the gelation of tung oil is the result of a gradual polymerization.<sup>107</sup> It is true that large amounts of oxygen introduced into linseed oil will cause complete solidification, but the product in this case is a somewhat soluble oxygenated substance, rather than a relatively insoluble polymer.<sup>108</sup> Extraction of oxidized linseed oil with petroleum ether removes the most soluble constituent, namely the unreacted linseed oil.<sup>109</sup> The soluble portion is found to be in the unimolecular state, while the insoluble material is definitely colloidal.<sup>110</sup> Rapid polymerization of linseed oil in the presence of oxygen is said to lead to the formation of undesired hydrophilic compounds. These can be avoided by the use of stand oils prepared in the absence of air.<sup>111</sup>

An interesting study of the role of oxygen in the polymerization of oils was reported by Scheiber.<sup>112</sup> He noted a superiority in the film-forming properties of oils containing conjugated double bonds. The rate of drying of tung oil, which contains a conjugated system, is not markedly decreased by the addition of anti-oxidants. He therefore reasoned that the autoxidation of linseed oil is accompanied by a rearrangement of double bonds to form a conjugated system. The effect is absent when oxygen is excluded, but the amount required is very small, and its influence is definitely catalytic.<sup>113</sup>

While these polymerizations usually occur in the presence of oxygen, by certain special procedures they may be carried out in the atmosphere of an inert gas. A novel method for the thickening of fatty and mineral oils is the "voltolization" process, which consists in subjecting the oil to the effects of an electric glow discharge of about 4000 v. at 500 cycles.<sup>114</sup> The voltage and frequency may be varied within rather wide limits.

Vehicles for lacquers and paints may be obtained by heating drying oils until they reach an iodine number<sup>115</sup> of 110 to 95 and treating the product with a hot alcoholic or ester solvent. Upon cooling the solution, an oil useful for lacquers and paints separates. Linseed oil, for example, which has been heated at 300°C. in the absence of air, is stirred with malonic ester.<sup>116</sup> This treatment extracts the

unpolymerized portion of the oil. Media for oil varnishes and enamels, which have been given the trade name, "Tekaoils," consist of linseed stand oils from which the low-polymerized, highly dispersed portion has been removed. They do not oxidize on exposure, but polymerization is pronounced. Tekaoil films dry more rapidly than stand-oil films and are more durable; also, it is said that zinc white and titanium white settle much less rapidly in Tekaoils than in stand oils of the same viscosity. "Olovine" varnish is prepared by heating Tekaoil with a polyvinyl ester (acetate).<sup>117</sup> Olovine in butyl acetate can be used in conjunction with nitrocellulose.<sup>118</sup> Heating linseed oil at about 300°C. until an iodine value of approximately 180 is reached, followed by air-blowing, results in products for paints and varnishes.<sup>119</sup> Mixtures of castor and linseed oils may be treated in the same manner at 75-150°C.

A molecular still which has been suggested<sup>120</sup> for the separation of constituents of polymerized drying oil consists of concentric tubes placed close together. The oil is caused to evaporate from the inner tube, which is heated, to the outer tube, which is cooled. The process is carried out at a pressure as low as the vacuum of a cathode tube.

Auer<sup>121</sup> noted that "isocolloid" materials containing unsaturated high-molecular fatty acids undergo a physical or physico-chemical change on heating with so-called "electrolytes" (salts, metallic organic derivatives and lower organic acids). The effect is to convert liquid materials into solids, or, conversely, to develop thin or pasty liquids from resinous substances. A variety of glyceride oils may be so modified, e.g., castor, olive, sunflower, tung, linseed and fish oils, by treatment with 2-10 per cent of a wide range of reagents.<sup>122</sup> Included are inorganic substances, e.g., silica gel, fuller's earth, sodium bisulphite and a considerably longer list of organic substances, e.g., formaldehyde, phenol,  $\alpha$ -naphthol, pyrogallol, thiocarbonyl, benzidine, 2,3-hydroxynaphthoic acid, benzene and glycerol. Use of an electric current during heating aids in bringing about modification.

Water-insoluble "modifiers" are used to prepare waterproof varnish bases, and gas-generating materials (carbonates, sulphites) are utilized for production of rubber substitutes.<sup>123</sup>

Substances applicable for the manufacture of soaps, varnishes and linoleum are secured by heating unsaturated fatty acids with peroxides, oxides or hydroxides of alkali metals.<sup>124</sup> Products of desired solubility and viscosity are obtained by addition of o-nitro phenol, p-cresol or benzoic acid.<sup>125</sup>

By oxidizing oils containing glycerides of unsaturated acids, and condensing the product with a polyhydric alcohol, condensation products are formed.<sup>126</sup> Treatment of a mixture of linseed and tung oils with zinc oxide and adding sufficient

benzoic or cinnamic acid to combine with all the zinc yields lustrous plastic masses.<sup>127</sup> Poppyseed or other drying oils may replace the linseed or tung oil.<sup>128</sup> For use in printing inks and artists colors, the addition of hexamethylenetetramine is recommended.<sup>129</sup>

A number of catalysts other than oxygen or alkaline materials have been used to assist the polymerization of drying oils. Finely divided metals, platinum, copper, palladium, iron, nickel or cobalt, accomplish the result at elevated temperatures.<sup>130</sup> Unsaturated oils heated at 250-300°C., in the presence of sulphur dioxide, hydrogen sulphide, carbon dioxide or hydrogen, under a reduced pressure of 15 to 145 mm., give polymerized oils,<sup>131</sup> which, when heated with a soap and vulcanized, are converted into rubber substitutes. These, in turn, are incorporated with solvents, fillers, cellulose esters and plasticizers to serve as varnishes.

Diolefins are also said to be polymerizable in mixture with glyceride oils (linseed, tung, castor or train oil) in the presence of aluminum chloride at ordinary or higher temperatures. The rubber-like product is extracted with solvents.<sup>132</sup>

Ott and Schüssler<sup>133</sup> treated unsaturated fatty acids or their esters or amides simultaneously with a sulphite and an oxidizing agent without the addition of acid. Compounds of cobalt, lead, manganese or iron may be added. Thus linseed oil heated at 100°C. for 16 hours with a 38 per cent solution of sodium bisulphite in the presence of air and lead-manganese naphthenate gave products soluble in water, and useful for dressing natural or artificial silk, and as wetting or greasing agents.

Stubner<sup>134</sup> employed an unsaturated fatty acid derived from tung oil (or from linseed oil) as a solvent for shellac or other gums, obtaining in this way a plastic insulating material, suitable for covering cables.

Reactions between fatty acids and various amino compounds have yielded substances useful in shoe polishes, floor dressings and similar products. Thus, p-aminophenol and oleic acid combine to form a black, waxy substance, soluble in most organic solvents.<sup>135</sup> Linseed oil or tung oil heated at 200-250°C. with 2 to 10 per cent of a primary aromatic amine yields a product which may be vulcanized, and finds use in varnishes and in rubber substitute manufacture.<sup>136</sup> Phenols may be condensed with the higher unsaturated fatty acids or glycerides in the presence of sulphuric acid.<sup>137</sup>

Treating linseed oil so that it dries essentially by the evaporation of a stabilizing solvent, ethanol, results in a product which can be incorporated in nitrocellulose lacquers to eliminate many of the weaknesses of ordinary blown or heat-treated oils.<sup>138</sup> Halovinyl compounds, vinyl acetylene<sup>139</sup> or vinyl naphthylene, in combination

with stand oils, give polymerized products<sup>140</sup> from which lacquers can be manufactured.

Paints and leather preservatives based on the treatment of linseed oil with a solution of chromyl chloride followed by the removal of the latter by distillation *in vacuo*, are stated<sup>141</sup> to be unsatisfactory. Other chlorides which have been used with linseed oil to produce vehicles for paints are titanium tetrachloride and silicon tetrachloride.<sup>142</sup>

The unsaturated fatty acids from Japanese sardine oil are polymerized by heating at 240-320°C., with the formation of resinous substances. Evidence suggests that an extramolecular polymerization is preceded by some type of intramolecular change such as ring formation.<sup>143</sup>

#### CASHEW-SHELL OIL RESINS

The oil extracted from the shell of the cashew nut contains anacardic acid ( $\text{HO}-\text{C}_{21}\text{H}_{37}-\text{COOH}$ ) and cardol ( $\text{C}_{32}\text{H}_{52}\text{O}_4$ ) which is probably a phenolic compound.<sup>144</sup> The commercial fluid is heat-treated, a process which destroys the anacardic acid. The chief constituent of the heated liquid has been named cardanol and assigned, tentatively, the formula

Formerly the oil was a waste product, but Harvey<sup>145</sup> has developed its use as a raw material for the manufacture of varnishes and impregnating materials known as "Harvel," "Oil Stop" and "Cardolite," and it now has a considerable commercial significance.

The principal source of crude cashew-shell fluid is India, but Portuguese East Africa, Cuba, Guatemala and Brazil are potential suppliers. The raw oil has a high iodine value (270-290), but despite this it is non-drying. This may be due to the anti-catalytic action of the phenolic constituents.<sup>146</sup> The iodine value of the commercial fluid is about 260. Although thin films of the oil remain unchanged when exposed to air for some time, oxygen absorption occurs rapidly once it has been initiated.<sup>147</sup>

The application of the oil is based on two important characteristics. It polymerizes on heating at 100-200°C. with an acid or alkaline catalyst; and it forms condensation products with aldehydes, probably because of its phenolic components. Harvey's view of the polymerization of cashew fluid in the presence of sulphuric acid postulates addition of the latter to the double bond of cardanol and subsequent elimination of sulphuric acid between two molecules as follows:

<sup>147</sup> M. T. Harvey, *loc. cit.*

If equal volumes of the oil and 40 per cent formalin are heated at 100-200°C. with 16 per cent of the total volume of hydrochloric acid, a liquid is formed which can be separated and heated at 80-140°C. under pressure to give a hard, molded body. In another method, a compact article is produced by impregnating layers of textile material with a varnish made from the formaldehyde-cashew fluid condensate. For this purpose, the varnish may include 25-35.5 per cent tung oil and 12.5-25 per cent rosin.<sup>148</sup>

Prior to the preparation of a molding composition, the cashew-shell liquid may be heated to about 300°C. and then cooled to room temperature. A mixture of the treated oil with 0.1 of its weight of paraform and about 0.9 of its weight of wood flour is molded and then cured at 140°C. for 5 hours. Instead of molding this composition, it may be employed with paper in the preparation of rolled laminated tubing, which is cured for 16 hours at 140°C. A similar procedure is applicable with hexamethylenetetramine substituted for the paraform. Only about one-third as much tetramine as paraform is required. In the case of hexamethylenetetramine, the reaction product is liquid, and dippings or coatings may be made prior to the cure.<sup>149</sup> For some purposes it is desirable to add pitch or casein to the composition.<sup>150</sup> Hardwood pitch and heat-treated cashew fluid form a petroleum-insoluble composition that can be utilized for coating or impregnating.<sup>151</sup>

A substitute for shellac is obtained by heating cashew-shell oil to 140-200°C. with copper, aluminum or lead or the oxides, hydroxides and carbonates of these metals. A liquid product is separated from the metallic compound, dissolved in alcohol or naphtha and used as a varnish.<sup>152</sup> The liquid material also has drying properties and may be employed for coating and impregnating.<sup>153</sup>

The non-drying characteristic of the oil may be eliminated, as noted above, by heating with metals or metallic compounds, and the rate of drying of the product is found to be controlled by (1) the temperature and time of the reaction and (2) the metal or salt employed. A drier, such as manganese resinate, may be incorporated with the cashew-shell fluid.<sup>154</sup> Copper can be coated with an insoluble insulating material by covering it with heat-modified cashew-shell liquid (drying oils and resins may be included) through the medium of a varnish solvent. Formaldehyde, hexamethylenetetramine or urea can be added to assist in the setting of the coat.<sup>155</sup> Cashew-shell oil, when heated and air-blown in the presence

of copper, lead, manganese, lead oxide, copper carbonate or copper oleate, combines with aldehydes to give resins that find use in varnishes. Materials including waxes and resins are added to vary the characteristics of the product.<sup>156</sup> A water-proofing composition for walls was reported to have been secured by treating cashew-shell oil with sufficient alkaline material (barium hydroxide, cement) to react with free acid and glycerides.<sup>157</sup>

The action of nitric acid on cashew fluid converts the latter into a quick-drying coating material which is soluble in amyl acetate, turpentine or alcohol.<sup>158</sup> To carry out this reaction, 1 part by volume of cashew-shell oil, 1 part of nitric acid (sp. gr. 1.42) and 1 part of water are mixed. The reaction is strongly exothermic and is complete in a few minutes. The resinous product formed has an iodine value of zero.<sup>159</sup>

Artificial rubber compositions are formed when cashew fluid is heated with glycerol at 240°C. The products may be vulcanized with sulphur, giving an

*Courtesy Louisville Drying Machinery Co.*

FIG. 166.—Air Dryer for Plastic Materials.

elastic material soluble in the usual rubber solvents.<sup>160</sup> A composition applicable in electrical insulation is prepared by mixing rubber with vulcanized cashew-shell oil and continuing the vulcanization.<sup>161</sup> Cashew-shell oil has been proposed also as a plasticizer for cellulose products, sulphur, resins, rubber and waxes.<sup>162</sup> Tung oil containing 25 per cent of cashew-shell liquid may be heated to 315°C. without risk of gelation, yielding a varnish base with copper oleate. The shell liquid can also be employed to reclaim overheated gelled tung oil,<sup>163</sup> for it redisperses the gel, forming compositions utilized as varnish bases.<sup>164</sup> A substance having germicidal properties may be obtained from cashew-shell oil. Thus, Harvey<sup>165</sup> distilled the

liquid (b.p. 305-400°C.) and heated the distillate with 0.2 per cent sodium hydroxide at 150°C. After redistillation, the water-soluble portion of the residue (a sodium salt of a high-molecular-weight phenol) serves as a germicide.

A series of coloring materials ranging from deep red to violet can be prepared by the interaction of cashew-shell oil with ammonium hydroxide or carbonate. The colored product is thickened by hydrochloric acid or formaldehyde, and can then be used for coloring oils or dyeing oilcloth.<sup>100</sup>

The importance of cashew-shell fluid is illustrated by the diversity of its applications. Washers for bottles or jars containing foodstuffs, cosmetics, mayonnaise, etc. are prepared by running paper through the cashew-shell liquid and then through a heated tower. Two or more coats are applied in this manner, and the paper is backed with paper-pulp board and punched into disc form. Compositions containing cashew-shell oil are also used to impregnate cloth or paper for electrical insulation, as baking-type varnishes and as acid-resistant paints.

A slowly polymerizing composition is applied in airplane magneto insulation. Cashew fluid is first partially polymerized by treatment with sulphuric acid, giving a thickened oil which hardens spontaneously to a resinous mass on the addition of paraformaldehyde. The time of the spontaneous cure can be regulated by the acidity of the composition. The partially polymerized cashew liquid is mixed with paraform immediately before use and pumped under pressure into the magneto where it is allowed to harden at room temperature. A somewhat similar material is applied as a lining for electrolytic tanks employed in copper and silver refining. Semi-solid masses with additions of asbestos may be troweled upon the surface and allowed to harden. The cure takes place without the application of heat.

One advantage found in the cashew-shell liquids is the oil-resistance of their polymers and formaldehyde reaction products. Oil Stop, a black, viscous liquid developed from cashew oil, is extensively used with paraform in cable splices. The paraform is incorporated with the liquid and coated over a lead splicing-sleeve. Alternate layers of cotton tape and Oil Stop are built up forming an oil-tight, waterproof seal. The seal can be applied to rubber, metal or paper.

Highly polymerized cashew-shell liquid (Cardolite) may be compounded with rubber and is used in typewriter rolls, brake linings and as a protection against corona discharge on rubber insulation. Brake linings can be manufactured by laminating thin sheets of partially hardened rubber with Cardolite and sheets of asbestos. In another method, a composition consisting of partially polymerized Cardolite, rubber cement and asbestos fiber is forced out of an extrusion apparatus.

#### MISCELLANEOUS COMPOSITIONS

Many oils other than those which have just been considered also have polymerizing properties. For instance, Gardner<sup>107</sup> found that the oil from oiticica seeds bodies rapidly on heating, although less rapidly than tung oil. The fatty acids of oiticica oil are more soluble in turpentine, butyl alcohol and ethyl acetate than the acids from tung oil, but less soluble in ethyl alcohol and mineral spirits. The heat-treated oil has been recommended for making linoleum, factice and airplane finishes.<sup>108</sup> The potential use of oiticica oil in varnishes is more or less dependent on its availability. The oil from the seeds of *Sterculia foetida* (Bangor nut) can

<sup>100</sup> M. T. Harvey, British P. 272,509, 1926, to Harvel Corp.; *Chem. Abs.*, 1928, 22, 1862.

<sup>108</sup> R. Lüde, *Fettechem. Umschau*, 1935, 42, 4; *Chem. Abs.*, 1935, 29, 2002; *Brit. Chem. Abs. B*, 1935, 304.

be heat-treated to form a composition for coating metals.<sup>160</sup> A different type of resinifiable substance is that which was obtained by Lifschutz<sup>170</sup> from the unsaponifiable matter of wool-fat. Loeschigk<sup>171</sup> utilized the foots obtained in refining cottonseed oil and similar products (consisting of soaps, neutral fats, resins and albuminous substances) by oxidizing with peroxide. After the addition of acid the fatty matter is recovered by means of solvents, and the remainder is an amorphous, resinous mass. Cotton oil also finds use in the manufacture of a plastic material for molding accumulator vats.<sup>172</sup> A composition is made which consists of cotton-oil residues (40 per cent), petroleum tar (20 per cent), kieselguhr (30 per cent) and asbestos or jute (10 per cent).

The fatty acids of drying oils can be esterified with quebrachitol, using a solvent and a catalyst, to procure modified products capable of thickening by heat or blowing with air.<sup>173</sup> These are said to be adaptable for paints and varnishes. A coating composition was developed by Albrecht<sup>174</sup> by heating triethanolamine with a fatty acid until esterification was complete, then adding phosphoric acid. An ester-phosphate compound is formed, which is reported to be of value in paints and varnishes for metal, in that it introduces the phosphate in soluble form.

Sandal seed oil thickens to a resinous mass on exposure to light. At 130-140°C., sulphur is absorbed and plastic rubber-like compounds are formed.<sup>175</sup>

A number of resinous materials can be made by treating fatty substances with higher alcohols. Thus, Brosel<sup>176</sup> treated fatty acids and esters with carnaubyl, cetyl or melissyl alcohol in the presence of litharge (which saponified a portion of the fatty acids to form lead soaps which acted as driers) to obtain rubber-like masses which could be dissolved in solvents to form varnishes. The catalytic oxidation of hydrocarbons<sup>177</sup> produces hydroxy acids which can be dehydrated to form unsaturated acids. These, in turn, are esterified with glycerine and may be oxidized to products resembling linoxyn.<sup>178</sup>

A "reinforced" oil<sup>179</sup> is made by heating a vegetable drying oil at 200°C. until it is substantially "deglycerolated," and then treating the residue with a quantity of glycerol in excess of that removed. The mixture is now heated with an acidic resin until the product has the desired degree of clarity and consistency.

Esterification of unsaturated fatty acids with polyvalent phenols (in the presence of zinc or aluminum chloride) yields products resembling oriental lacquers.<sup>180</sup> These compositions can be modified by condensation with formaldehyde.<sup>181</sup> Under the influence of boron fluoride unsaturated fatty acids react with phenols to form viscous compositions which may be drawn into threads.<sup>182</sup> Linseed oil with resorcinol and catalytic quantities of hydrogen chloride gives viscous condensation prod-

ucts of intense red color.<sup>188</sup> For the preparation of sizing materials it is suggested that the linseed oil be sulphonated during condensation with resorcinol.<sup>184</sup>

Ferrous linoleate is soluble in turpentine and in dichlorobenzene, and this solution has been used as the basis of a paint medium.<sup>186</sup> When linseed oil is heated at 180-200°C. with acid sludge or acid resins from the refining of mineral oils it forms linoleum-like plastic masses.<sup>186</sup>

Diesser<sup>187</sup> prepared a resinous body by heating cellulose with fatty oils. Scholz<sup>188</sup> found that a plastic composition is obtained when a mixture of linoxyn (free from solvents) and nitrocellulose (swelled in a volatile solvent such as ethyl acetate) is stirred until homogeneous and then molded under pressure.

Resinous substances are obtained by dissolving old varnish or resin coatings in solutions of sodium or ammonium carbonate or hydroxide, sodium borate, etc., and treating the solution with sodium hypochlorite or free chlorine. The resin is precipitated by sulphuric acid or sulphur dioxide, and the dried precipitate is used in the preparation of varnishes.<sup>189</sup> Horn scrap is reported to be soluble in linseed oil at 300°C., and the solution has been proposed for use as a paint vehicle and as a varnish.<sup>190</sup>

## Chapter 62

# Inorganic Resins

Although almost all resinous materials are natural or synthetic carbon compounds, containing no other elements than oxygen, hydrogen and perhaps nitrogen or sulphur, there is a small group of inorganic resins. For example, silicic acid gels, as well as glass, exhibit some of the properties of organic plastics. (See Chapter 3.) However, the present chapter deals, in the main, with organic compounds of silicon which, although exhibiting many of the characteristics of silicates, are definitely resinous in character. Some of them are soluble in organic solvents. In reviewing the most important inorganic resins, including compounds of silicon, germanium, phosphorus, boron and thallium, it should be borne in mind that they have, despite their rarity, potential commercial significance.<sup>1</sup>

### SILICA

Diatomite and coal when heated together give a product called silica black. Jacobson<sup>2</sup> heated a mixture of silicon dioxide and finely ground coal in a 1-quart iron retort at 600-700°C. for 4 hours. Of the black pulverulent material left in the retort, 43 per cent was fine enough to pass a 200-mesh, and most of the remainder a 100-mesh sieve. The product was not a mechanical mixture but was amorphous and had a composition of 18 per cent carbon, 75.5 per cent silicon dioxide and 6.5 per cent oxides and sulphides. Silica black is insoluble in water and the usual organic solvents. It acts as a clarifier and decolorizer and may be used in ink, stove polish and as a carrier for insecticides.

When silicic acid is dehydrated with heat, a colloidal mass of silicon dioxide known as silica gel is formed. The elasticity and plasticity of acid, neutral and alkaline types of this substance can be measured by bending tests.<sup>3</sup> For samples of the same age, the elastic properties are similar; but the plasticity and shrinkage increase continuously from the acid to the alkaline gels. The freezing-point depression, viscosity, and electrical conductivity of purified sols of silicon dioxide have been determined.<sup>4</sup> From the results it appears that gelatinization begins with polymerization of simple molecules, accompanied by a decrease in the number of free hydrogen ions, the polymerized molecules afterwards coagulating to form a network which imbibes the whole of the liquid. Similarly, other investigators,<sup>5</sup> after a study of viscosities of silicic acid solutions, report that solutions from more highly polymerized esters gel more quickly.

The alkyl silicates are important because of their application in silicon-ester paints. The method of preparing ethyl orthosilicate, which was discovered by

<sup>1</sup> Stacol, an inorganic resin manufactured by Glyco Products, Brooklyn, was put on the market in 1933 (*Plastics*, 1933, 9, 373).

<sup>5</sup> R. Signer and H. Gross, *Ann.*, 1932, 499, 158; *Brit. Chem. Abs. A*, 1933, 23. See L. A. Jordan and J. O. Cutter, *J.S.C.I.*, 1935, 54, 89T.

Ebelmen,<sup>6</sup> has been improved by Dearing and Reid.<sup>7</sup> Silicon tetrachloride, free from higher-boiling compounds, is added dropwise to anhydrous alcohol cooled in a freezing mixture and present in 10 per cent excess to insure the reaction of all the chlorine.

The ester is then fractionated in a vacuum, water being carefully excluded, to give a 70 per cent yield. Other alkyl orthosilicates have been prepared in the same way.<sup>8</sup>

A shallow layer of ethyl orthosilicate reacts readily with water vapor, or water diluted with alcohol, to yield silica gel. A non-aqueous gel is prepared by refluxing a mixture of 4 parts of acetic acid to 1 part of the ester for an hour and allowing it to stand overnight. Excess acetic acid is removed by immersion in dry benzene.

In the alkyl orthosilicate formation from silicon tetrachloride and alcohol, variable quantities of high-boiling, viscous substances are also obtained.<sup>9</sup> Treatment of 1 mol of methyl orthosilicate with 0.5 mol of water leads almost exclusively to the formation of the disilic ester

An increase in the ratio of water to ester results in a compound of the type

in which  $x$  is a function of the ratio. Using 1 mol of water to  $\frac{1}{2}$  mol of alcohol, a product having an approximate molecular weight of 10,000 is obtained.

Inasmuch as alcoholic solutions of silicon esters react with water to form colloiddally dispersed silicon dioxide, silicon-ester paints are feasible. Hydrolyzed silicon esters, which contain about 9 per cent silicon dioxide, penetrate stone yielding a hard protective silica gel.<sup>10</sup> The paint medium is prepared by stirring 351 l. of a solvent ester into 50.7 l. of water in 135 l. of 94 per cent alcohol until solution is obtained and then adding 250 l. of the silicon ester.<sup>11</sup> Titanium dioxide, earth colors or other non-basic pigments are incorporated, and the solution can then be preserved in sealed containers. The essential feature of the paint is its property of hydrolysis, resulting in a coating of silica.<sup>12</sup> The advantages, it has been stated, are that it is compatible with wet plaster, heat resistant, does not blister, is easy to clean, porous (permits breathing of the surface), easy to work and economical. The disadvantages are that it does not adhere to distempers and oil paints and is difficult to store.

The best method of applying a silicon-ester coating is by means of a spray,

although spreading with a brush is satisfactory.<sup>13</sup> Initial setting, depending on the amount of diluents and atmospheric moisture, takes place in approximately an hour; final setting, which is the completion of the hydrolysis, requires a longer period.

Esters have also been employed in solution as binders in the preparation of porous objects made by mixing powdered silica with calcium carbonate<sup>14</sup> and in the manufacture of insulators from small pieces of mica.<sup>15</sup> In the latter case, methyl orthosilicate in alcoholic solution is hydrolyzed to give an adhesive material which is incorporated with the mica, and the whole is heated under pressure, forming a solid mass.

Oily and viscous silicyl compounds have been prepared<sup>16</sup> by reaction between hydroxycarboxylic acid esters and silicic acid alkyl esters. For example, 10 parts of ethyl ricinoleate are heated with 2 parts of ethyl orthosilicate in a closed container at 150°C. The resulting alcohol and excess ethyl orthosilicate are distilled off *in vacuo*; the product is taken up in ether, washed with water, dried with anhydrous sodium sulphate and the solvent evaporated. The reaction may be written as follows:

Silicon tetrachloride reacts with cyclohexanol to form trichloro-cyclohexanoxy-, dichloro-di(cyclohexanoxy)-and monochloro-tri(cyclohexanoxy)-silicon.<sup>17</sup> The polymeric esters were prepared by shaking the monomolecular esters in absolute ether with dry silver carbonate. The trichloride gave a product of the formula

as a white amorphous mass. The dichloride yielded a solid

and an oil

The monochloride formed a compound with the formula

Kipping and his co-workers in their work on silicon have discovered a number of complex compounds, some of which are amorphous or gluc-like. These will be discussed without any attempt to outline their chemistry in detail.

The action<sup>18</sup> of sodium on diphenylsilicon dichloride in toluene solution gives sparingly soluble compounds of the formula  $[\text{Si}(\text{C}_6\text{H}_5)_2]_n$ . In addition a glue-like, readily soluble material is formed. It is believed to be amorphous octaphenyl-cyclosilicotetrasilane,<sup>19</sup> the crystalline form of which is only slightly soluble in cold acetone. The sparingly soluble silicohydrocarbon is converted by diphenylsilicon

<sup>16</sup> H. Kaufmann, U. S. P. 1,918,338, July 18, 1933; *Chem. Abs.*, 1933, 27, 4879.

<sup>17</sup> R. Signer and H. Gross, *Ann.*, 1931, 488, 56; *Chem. Abs.*, 1931, 25, 5188.

<sup>18</sup> F. S. Kipping and J. E. Sands, *J.C.S.*, 1921, 119, 830.

<sup>19</sup> F. S. Kipping, *J.C.S.*, 1927, 2719.

dichloride into glue-like products.<sup>20</sup> This action takes place only with the reagent itself and does not occur in a diluent, e.g., toluene. The amorphous form of octaphenylcyclotetrasiloxane, dissolved in acetone and treated with alcohol, forms a white plastic precipitate which can be pulled out into long silk-like threads, but these become brittle when the solvent evaporates. The residue from the destructive distillation of the amorphous material, when cold, is a brittle honey-colored resin, insoluble in all the common solvents.<sup>21</sup> If treated with cold chloroform, a small proportion separates in the form of yellow flakes.

Di-*p*-tolylsilicanediol in 5 per cent sodium hydroxide solution precipitates a gluey condensation product.<sup>22</sup> Similarly, when diphenyltolylsilicanediol is treated with hot potassium hydroxide, complex amorphous condensation products are obtained.<sup>23</sup>

Dibenzylsilicon dichloride yields, on heating with sodium in toluene, a small amount of tribenzylsilyl oxide and tetrabenzylsilicane, and a large amount of octabenzylsilicetetran oxide,  $[\text{Si}(\text{CH}_2\text{C}_6\text{H}_5)_2]_4\text{O}$ , a resinous mass.<sup>24</sup> The latter, when precipitated as an oil from its acetone solution with alcohol, hardens to a solid resin. From chloroform, it separates as a blood-red resin, which on treatment with acetic acid forms a colorless, glue-like mass. Octabenzylsilicetetran oxide is also obtained as a highly lustrous, flaky solid by frothing its ethereal solution.

Phenylsilicon trichloride, dissolved in xylene, reacted in a sealed tube at 150°C. with sodium to give a small amount of insoluble and some soluble material. The latter was a pale yellow resin, fractionation of which gave a series of colorless powders and gelatinous substances.<sup>25</sup> They either charred or liquefied over a wide temperature range. Further examination showed that an increase in oxygen content of the compound decreased its solubility in organic solvents. Molecular weight determinations on the xylene-soluble resins gave values between 900 and 9000, corresponding to 6 and up to about 50 silicon atoms in the molecule.

The formation of a similar series of products by the action of sodium in boiling toluene on di-*p*-tolylsilicon dichloride has also been studied.<sup>26</sup> Another illustration of a reaction giving amorphous materials is that occurring between cyclohexyl magnesium bromide and silicon tetrachloride. When the reagents are heated together in ether and distilled at 3-4 mm., cyclohexylsilicon trichloride and dicyclohexylsilicon dichloride are collected. The residue is very viscous and dissolves in ether. On continued heating, frothing occurs and the contents of the flask gradually become solid.<sup>27</sup>

Kipping and Blackburn<sup>28</sup> studied the nitration of tetraphenylsilicane in carbon tetrachloride solution in the absence of sulphuric acid. Ten per cent of the product isolated was a tetranitro derivative which appeared to be tetra-*m*-nitrotetraphenylsilicane, melting at 255°C. The remainder of the crude nitration product was readily soluble in acetone, from which it separated in a glue-like form. From aqueous methyl, ethyl and isopropyl alcohols, however, a colorless powder melting at 90-110°C. was obtained. This, under high magnification, seemed to be composed of globular transparent particles. Their composition approximated that of the tetranitro derivative.

<sup>28</sup> F. S. Kipping and J. C. Blackburn, *J.C.S.*, 1932, 2200.

When diphenyl- and dibenzylchlorosilicane were treated with mercuric oxide, diphenyl- or dibenzylsilicone were not formed but rather thick glue-like substances, soluble in many organic solvents, resulted.<sup>29</sup> These compounds correspond most closely to the following molecular formulas:

Reviewing the compounds of silicon as a group, two reasons for the occurrence of resinous products may be advanced: The first is the tendency of silicon atoms to form chain-like molecules. The second and perhaps the main reason is the presence of organic radicals in the molecule. The further development of the organic chemistry of silicon may lead to the production of cheap and readily prepared derivatives which can be applied as resins or binding agents.<sup>30</sup>

### TITANIUM COMPOUNDS

A number of titanium esters have been prepared, corresponding to the silicon esters already described. Gardner and Bielouss<sup>31</sup> prepared ethyl titanate by the dropwise addition of titanium tetrachloride to a cold solution of sodium ethoxide, with subsequent refluxing. The product was soluble in alcohol, benzene and toluene. Titanium compounds of glycerol and glycol of varying composition were also obtained by the slow addition of titanium tetrachloride to an excess of the corresponding polyhydric alcohol at 80-145°C. The products were soluble in water and alcohol, but not in toluene.

Films of ethyl titanate applied to various surfaces and hydrolyzed *in situ* were unsatisfactory, because they lacked adhesion and continuity. A white-pigmented lacquer was formed on adding titanium glycolate in alcohol (1:4) to a solution of nitrocellulose in butyl acetate. The titanium compound is hydrolyzed under these conditions, forming titanium dioxide.

### GERMANIUM COMPOUNDS

Schwarz and Lewinsohn<sup>32</sup> have made a number of compounds, which suggest the possibility of forming amorphous substances from germanium, among which is the germanium-phenyl ring compound similar to benzene,

This compound was made by the action of metallic sodium on phenylgermanium trichloride in xylene. Monophenyl germanium ( $\text{C}_6\text{H}_5\text{Ge}$ ) was formed, which in turn readily polymerized to form the ring already shown. Germanium tetrachloride reacts with 4 mols of aniline to yield aniline hydrochloride and germanium diphenyldiimide dihydrochloride,  $\text{Ge}(\text{NC}_6\text{H}_5\text{HCl})_2$ , a glassy non-crystalline solid.<sup>33</sup>

## PHOSPHORUS COMPOUNDS

Among the more important resins containing phosphorus are those derived from phosphorus nitrile chloride,  $\text{PNCl}_2$ . Stokes<sup>34</sup> found that when the latter was heated, it polymerized to give rubber-like material. Crude phosphorus nitrile chloride is a buttery mass made up of the primary crystalline bodies,  $(\text{PNCl}_2)_3$  and  $(\text{PNCl}_2)_4$ , together with oily polymers. The latter, when heated at  $200^\circ\text{C}$ ., rapidly yield elastic masses. The crystalline bodies, however, polymerize slowly at  $255^\circ\text{C}$ .; and when the melt is heated for 4 hours at this temperature, it becomes turbid and viscous. On cooling it is amorphous and kneadable like paraffin. The resultant mass melts at  $200^\circ\text{C}$ . After 6 hours heating, polymerization is complete and an inorganic rubber is obtained as an elastic mass. It will no longer melt; and if it is heated to redness, it becomes hard and brittle on cooling. The elastic product, in the pure state, is colorless, transparent, and insoluble in common solvents. In benzene it swells, with the formation of a reversible sol. When it is allowed to stand in the air for a long time, it is transformed into a brittle substance.<sup>35</sup> In his study of the effect of varying degrees of heating on phosphorus nitrile chloride, Renaud<sup>36</sup> reported that some of the polymers have real and others apparent melting points. In the latter case there is a transition from a crystalline form to a clear gel. All of the forms of phosphorus nitrile chloride are brittle at  $-47^\circ\text{C}$ .

Light amber-colored inorganic resins for use in varnishes and insulations have been made by Runyan.<sup>37</sup> One mol of tricresyl phosphate<sup>38</sup> is heated to  $315\text{--}340^\circ\text{C}$  under reflux. At this temperature 3 mols of calcium oxide are added, the heating being temporarily suspended. As the vigor of the resulting reaction subsides, the temperature declines. When it falls to  $245\text{--}260^\circ\text{C}$ ., heating is resumed and continued until the reaction product, on cooling, solidifies to form a resin hard at ordinary temperatures. Trioxymethylene is added during resinification, in amounts corresponding to the phenol released. The addition of linseed oil (5-10 per cent of the weight of the resulting resin) confers toughness. The resin, it has been stated, may be used to impregnate fiber, which is subsequently molded under heat and pressure; or it may be employed in a varnish.

In an attempt to form homophthalyl chloride, homophthalic acid (1 mol) was heated with phosphorus pentachloride (10 per cent in excess of 2 mols) in phosphorus oxychloride as a solvent. The product obtained was 3-chloroisocoumarin. On the other hand, when homophthalic anhydride was substituted for the acid in the reaction, a tarry mass resulted.<sup>39</sup>

Cholesterol, in some of its reactions with phosphorus pentachloride, yields resinous products.<sup>40</sup> When the two substances are mixed in anhydrous benzene, there is an exothermic reaction with a slow steady evolution of hydrochloric acid, the solution meanwhile becoming reddish brown. After 24 hours, the product is washed with water, dried, the benzene evaporated and the residue recrystallized from acetone. There are obtained trichlorocholestane and an unidentified resin. With cholesterol and phosphorus pentachloride in a solid state, cholesteryl chlo-

and subsequent addition of lead acetate forms a lead salt,  $C_{18}H_{16}O_{12}Pb_2$ , which is a brittle, colorless mass.<sup>48</sup> Glassy masses have also been obtained from the potassium salt derived from allenetetracarboxylic ester.<sup>49</sup>

Thallium ethoxide in benzene, added to a hot solution of tetra-acetylpropane, yields a yellow-colored mass which rapidly turns red.<sup>50</sup> A brown substance precipitates which, on filtration, becomes resinous. Evaporation of the benzene likewise causes resinification of the residue.

## Chapter 63

### Miscellaneous Resins

This chapter has two purposes. First, it describes some of the applications of synthetic resins in which no particular resin has been specified or where there is presumed to be a latitude of choice. Second, it groups a number of resins which have not come under the scheme of classification adopted in the text. Resinous bodies have resulted in the course of reactions carried out in many researches with organic compounds. Such bodies generally are not the result of an effort to produce them but are none the less interesting to investigators working in the field of synthetic resins. At the time of discovery, it may not be practicable to prepare the substance in quantity by the reaction under investigation and yet under later economic conditions this reaction may be applied to commercial advantage. This chapter, therefore, represents so wide a range that but little attempt has been made at classification, and the reader will find it as heterogeneous as are the resins.

#### TECHNICAL APPLICATIONS

**Various Applications of Resins with Cellulose Derivatives.** Synthetic resins have found a number of applications in conjunction with cellulose derivatives, usually in the production of films.

A liquid- and moisture-proof, transparent and flexible material is formed by coating transparent foils of regenerated cellulose with a cellulose ester lacquer. With the latter is incorporated a solution of a solid or liquid wax or grease, and a natural or synthetic resin in a solvent which is miscible with the cellulose ester lacquer. The applied film is then exposed for a time to a temperature above the softening point of the waxes.<sup>1</sup> An insulating material can be prepared from mineral wool mixed with a binder made of nitrocellulose, cumarone resin, and a solvent.<sup>2</sup> Waterproofing substances, such as natural or synthetic resins, asphalts, paraffins or waxes may also be added to impermeable and insulating compositions made from nitrocellulose varnishes and triaryl phosphates.<sup>3</sup> An insulator resistant to heat, moisture and electricity is likewise obtained by applying a liquid insulating resin to a solid carrier of transparent regenerated cellulose obtained from viscose. The coating can be dried and solidified at any desired temperature.<sup>4</sup>

Surfaces made from insoluble and infusible resins have been suggested as bases for depositing cellulose acetate solutions in film manufacture.<sup>5</sup> Cellulose derivatives may be used similarly for coating spools used in the textile industries, the metal spools being first coated with a natural or synthetic resin.<sup>6</sup> Fibrous material and synthetic resin have also been employed for coating wooden shuttles.<sup>7</sup>

Iron, glass or wood surfaces may be covered with a synthetic resin modified by the addition of a cellulose derivative. Further applications of a cellulose ester can be made.<sup>8</sup> Coating compositions are prepared by dissolving cellulose acetate in a low-boiling vehicle consisting of ethyl alcohol, benzene, and ethylene dichloride. Resins, high-boiling solvents, plasticizers, pigments and fillers may then be incorporated.<sup>9</sup> Solutions containing methyl or benzyl cellulose, synthetic resins, plasticizers and stabilizers have been suggested also.<sup>10</sup> The addition of resins to a lacquer containing cellulose acetate, dibutyl tartrate and triphenyl phosphate dissolved in acetone is said to improve its strength and adhesive power.<sup>11</sup>

Synthetic resins of various types may be added in amounts between 1 and 25 per cent to cellulose ethers and esters to increase the tensile strength of artificial filaments, plastic compositions, and adhesives made therefrom.<sup>12</sup> Thus, simulated horse-hair, bristles or straw are prepared by extruding a solution of cellulose ester, resin and plasticizer into an evaporative atmosphere or a coagulating bath.<sup>13</sup> The addition of natural or synthetic resins, which melt above 250°C., to cellulose derivatives reduces the luster of the threads formed by spinning.<sup>14</sup> In the manufacture of artificial silk by the wet-spinning process, soluble synthetic resins are among the materials which may be added to the precipitating bath.<sup>15</sup>

Plinatus<sup>16</sup> employed natural or synthetic resins in conjunction with cellulose esters in the preparation of binders and adhesives. A fusible or soluble synthetic resin may be used also to secure adhesion between a plastic sheet of a cellulose derivative mixed with an organic tartrate, such as dibutyl tartrate, and two sheets of glass.<sup>17</sup> Synthetic resins in a reactive state may be applied to a porous carrier such as paper or fabric, or mixed with film-forming solutions (viscose or cellulose ester solution) to provide films or sheets for adhesive purposes.<sup>18</sup> A binding agent consisting of a solution containing 8-15 per cent of a cellulose derivative and a natural or synthetic resin can be employed in making a moisture-proof, match-igniting composition.<sup>19</sup>

By dissolving higher fatty acid esters of cellulose (such as cellulose distearate) in xylene, with the addition of fatty or mineral oils, waxes and artificial resins Lant and Koreska<sup>20</sup> have prepared varnishes for tennis-racket strings.

The flexibility of synthetic resins capable of being hardened is found to be preserved by incorporating alkyl celluloses.<sup>21</sup> Normally light-sensitive synthetic resins, or coatings containing them, can be darkened by exposure to ultraviolet light. Alternatively, the resin may be darkened during manufacture in the presence of benzoic or salicylic acid as catalyst. Coatings which contain such darkened resins together with cellulose derivatives, especially the acetate, do not change color on further exposure to light.<sup>22</sup>

**Impregnation of Cellulosic Material with Synthetic Resins.** The treatment of vegetable fiber with synthetic resins offers considerable scope for the fabrication of artificial wood and molded insulating material. For example, a resin-coated board can be obtained by applying a layer of synthetic fusible resin, mixed with fillers, to a fibrous spongy base containing a fusible binder with a low coefficient of expansion (e.g., asphalt). The whole is compacted, and the resin rendered infusible by heat and pressure.<sup>23</sup> In another case, saponified or emulsified hard waxes, such as Montan wax, either alone or mixed with other hard waxes or natural or synthetic resins, can be added to fibrous pulp in quantities up to 35-50 per cent of the weight of dry pulp. The material is then precipitated by the addition of alum, and the pulp-wax mixture is formed into sheets and molded.<sup>24</sup>

Samsonov<sup>25</sup> prepared artificial wood from vegetable materials such as reeds or cane trash with the fibers arranged in one direction, by immersing in a natural or artificial resin and then compressing. Fungicides were incorporated. The steps of solvent-extraction and resin-polymerization in synthetic resin varnish-impregnation processes for wood, tissue paper and cardboard may be conveniently carried out in dry steam. The latter carries away solvents which can subsequently be recovered.<sup>26</sup>

Vulcanized fiber may be impregnated with solutions of substances capable of forming synthetic resins. The development of the latter is thus effected within the material.<sup>27</sup> Regal<sup>28</sup> hydrolyzed paper with sulphuric acid and then treated it with an alkaline solution of a synthetic resin. Precipitation of the resin *in situ* gave an imitation parchment. If glassine paper, made from highly-beaten pulp, is impregnated with a solution of castor oil in benzene, dried, treated with a solution of resin, and dried again, it is rendered transparent, according to Chamberlain and Periam.<sup>29</sup> Flexible sheet material which can be used as a substitute for glass is made by coating gauze or netting with a homogeneous mixture of synthetic resin and cellulose acetate.<sup>30</sup> A paper for cigarette mouthpieces is made by treating thin tissue paper with a synthetic resin.<sup>31</sup>

Impregnation of cellulosic material with synthetic resins may be effected in the following manner: Wood shavings, leaves or woven fabrics, for example, are subjected successively to 1 per cent sodium hydroxide solution at 100°C. and to an aqueous solution of an oxidizing agent, e.g., 5 per cent sulphuric acid and nitric acid. The product is washed and dried after each operation, being finally neutralized with ammonia. It is then impregnated with a synthetic resin solution (or ingredients which will form resins), heated, and pressed to render the resin insoluble.<sup>32</sup> Another instance is the treatment of the fibrous material which is fed to the final presses in the manufacture of pressboard. The wet mass is soaked in alcohol, removed and immediately immersed in a synthetic resin. After drying it is then molded under heat and pressure.<sup>33</sup>

employs a thin coating of transparent synthetic resin to cover a sheet of paper, on which are colored ornamentations. This is applied to a main body portion of bituminous material. Furniture, boxes and similar articles made of wood, metal, paper-like or ceramic materials may be coated or lined with synthetic resin plates, carrying on the back an intermediate veneer which may be attached by cold casein glue or liquid resin.<sup>35</sup> Panels or backings for oil paintings can be made by impregnating a fibrous base, such as pulp board or superimposed sheets of paper or fabric, with a reactive synthetic resin, and subjecting the product to heat and pressure.<sup>36</sup> Keller<sup>37</sup> suggested synthetic resin compositions for backing advertising sheets and posters. In the painting of wood, use may be made of certain tar oils mixed with a cellulose ester solution and a solution of a natural or synthetic resin, with or without a pigment. The tar oil constitutes 30-50 per cent of the total mixture.<sup>38</sup>

One method of producing carbon paper is by spreading a solution of a synthetic resin on paper, evaporating the solvent and adding a color layer. Softening agents (oils or fats, ethyl phthalate or tricresyl phosphate) may be added to the resin layer.<sup>39</sup> Analogous compositions for transfer purposes comprise coloring substances together with synthetic resins or soluble cellulose products.<sup>40</sup> Horii<sup>41</sup> employed a similar process for the manufacture of stencil sheets. A base of fibrous material, such as yoshino paper, carries an impregnating composition containing a synthetic resin and a softening agent, e.g., stearin and castor oil.

**Applications of Synthetic Resins with Rubber.** Blankets for impression cylinders used in printing may be made of one or several layers of fabric impregnated with rubber, a thick coating of rubber and an outer ink-resisting coating of synthetic resin.<sup>42</sup> Quittner<sup>43</sup> developed a method for producing elastic, waterproof, adherent coatings by treating fibrous material with rubber latex and solutions or emulsions of synthetic resins. The latex and resin dispersions may be applied either jointly or successively.

Sheets made from synthetic rubber, synthetic resin and fillers may be used as substitutes for linoleum, celluloid or horn. Factice, natural rubber, cellulose esters and ethers and dyes may be included in the compositions.<sup>44</sup> A flexible material for making pipes, has the following composition: rubber, 40 parts, sulphur, 3 parts, synthetic resin, 25 parts, graphite, 20 parts, and fillers, 12 parts.<sup>45</sup> Lefebure<sup>46</sup> prepared a hose, resistant to gasoline and other organic solvents, by impregnating outer and inner plies of canvas with a resin, using an intermediate layer of rubber. He also made a rubber flooring by vulcanizing rubber sheets or tiles directly on an intermediate layer of wood, cement or stone which can be secured to a floor base. Synthetic resin binder is placed between the contacting surfaces of the materials.<sup>47</sup> Synthetic or natural rubber mixed with a resin and

fillers may be employed as an elastic filling composition for cracks or joints in concrete or wood paving and flooring.<sup>45</sup>

The application of synthetic resin globules with a diameter of less than 1 mm. imparts a frosted appearance or sheen to textile fabrics or rubberized goods.<sup>46</sup> A film of protein (treated to render it resistant to water) is utilized for the attachment of rubber to synthetic resins in the lining of vats, or for cementing tires to wheels.<sup>47</sup> Pratt<sup>48</sup> succeeded in developing a material having rubbery qualities by dispersing a terpene (dipentene, isoprene or their polymers) in water in the presence of a protective colloid. The terpene particles should be about the size of latex particles. The coating of protective colloid is then tanned to prevent rupture of the globules during milling. The product when coagulated forms a rubber-like mass capable of vulcanization. Natural or synthetic resin may be added to give an acetone-soluble constituent.

A coating of synthetic or natural resins may be precipitated on a metallic mold as follows: Dispersions of the substance to be deposited are stabilized by an inorganic acid, base or salt. The latter should be capable of reacting with some constituent in the mold in order to cause deposition of a layer of the agglomerated substance on the surface of the mold. Thus, a mold made of zinc or aluminum may be dipped into such a dispersion, and reaction of the alkali with the metal causes a deposit on the surface of the mold.<sup>49</sup>

**Various Coating Compositions and Impregnated Products.** A method of decorating sheet metal is carried out in the following manner.<sup>50</sup> The sheet is first treated with a coat of resins ground in oil and pigmented with colors. A printed or lithographed design secured to a gum coating on a paper backing is dipped in a liquid composed of ethyl lactate, ethylene chlorhydrin, ethyl alcohol and water. The design is then laid face down on the ground coat, pressed on it, the backing is removed and the decorated sheet is baked. It may then be formed into the desired shape. A suspension in tar oil of synthetic resins capable of being hardened also may be used for coating metals.<sup>51</sup>

The surface hardness of light construction materials, e.g., porous cement, can be increased by a coating of synthetic resin.<sup>52</sup>

Mixtures consisting of synthetic resins and liquid softening agents, such as triaryl phosphates, can be utilized in the preparation of electrical insulating compositions.<sup>53</sup> The coating of layers of paper or woven fabrics with synthetic resins offers a further way of building up such materials.<sup>54</sup> For example, electrical insulating sheets and tubing can be made from fabrics composed of "threads" of spun paper by impregnating with a varnish containing resins.<sup>55</sup> Tubes employed in spinning, or other articles made from fibrous material, may also be impregnated with synthetic resins.<sup>56</sup>

Envelopes for gas cells can be constructed from a material composed of one or more layers of an organic cellulose derivative soluble in organic solvents, and

one or more layers of a protein, e.g., casein, glue or gelatine. Softening agents, natural and synthetic resins and fillers may be incorporated.<sup>60</sup> Cellulose fibers, rendered moisture-proof by a varnish of synthetic resin containing a plasticizer, are employed in making dust-bags for vacuum cleaners.<sup>61</sup>

Varnish and lacquer coatings which are said to be resistant to shocks and blows can be produced by incorporating with synthetic resin solutions a hard material such as silicon carbide of grain size between 40 and 100 microns.<sup>62</sup> By dispersing a finely divided insoluble and infusible resin in a ketone or ketonic alcohol solution of a hardenable synthetic resin an enamel can be prepared which may be applied in the cold.<sup>63</sup> An interesting development in this connection is the production of waterproof sandpaper, since the ordinary product usually disintegrates when it becomes wet. A cement is used consisting of rosin (250 parts), glue (60 parts), 87 per cent phenol (75 parts), 56 per cent acetic acid (100 parts), water (100 parts) and benzene (5 parts). This, applied to a backing material, will hold abrasives and is flexible and waterproof. The composition is given a final treatment with formaldehyde solution, dried and coated with linseed oil.<sup>64</sup>

A mixture of fish scales with synthetic resins is recommended as a coating for preserving paint on ships or other articles coming into contact with sea water.<sup>65</sup> Guillemin<sup>66</sup> suggested compositions made by heating together natural or synthetic gums or resins, vegetable oil and added materials (e.g., turpentine, "white spirit" and lead oxide) as waterproofing agents for leather.

Mixtures which contain cellulose esters, graphite or mica, finely ground wood or cork, with additions of resin and pigment have been described as knifing compositions.<sup>67</sup>

Objects of acid-proof material can be constructed of wide-mesh fabric impregnated with liquid synthetic resins, and subsequently hardened by heat.<sup>68</sup> A fire extinguisher consists of a liquid which is a poor conductor of electricity (e.g., carbon tetrachloride, tetrachloroethane) together with aluminum sulphate, varnishes, lacquers and the like which will form a resisting insulating layer on the surface over which it is sprinkled.<sup>69</sup>

**Various Molded Materials.** The baskets or pots of centrifugal apparatus may be made by molding and vulcanizing a mixture of natural or synthetic rubber, sulphur and synthetic resins, with or without filling materials.<sup>70</sup> Another type of basket is constructed of annularly disposed cords, provided with a steel wire core, and bound together with synthetic resin.<sup>71</sup> Resins have also been used for making cages or retaining rings for ball and roller bearings.<sup>72</sup>

Panel plates of pressed synthetic resins, joined by grooved strips, pegs and screws of the same material may be used to build up vessels for holding acids and other liquids.<sup>73</sup> Boorne<sup>74</sup> made articles such as tiles and slabs by molding with heat and pressure a mixture of resin, clay, a basic material (lime), a filler (sand), and water. The process was adapted to give products with colored facings or with decorative "crazed" effects.

A magnetic insulating material can be produced by impregnating textile sheets with a mixture of synthetic or natural resin and fillings or fine powder of magnetic material. The sheets are piled and then consolidated under heat and pressure.<sup>75</sup> Powdered magnetic material can also be molded under pressure with magnesium hydroxide and a small quantity of natural or synthetic resin. Magnetic cores for loading coils and transformers are obtained in this way.<sup>76</sup>

Agglomerated horn products may be prepared by hydrating small pieces of horn with hot or cold water, drying superficially *in vacuo* at 15°C. or in an air current at 40-45°C., mixing with a synthetic resin, and then heating at 130-150°C.

in a mold under high pressure.<sup>77</sup> Oexmann<sup>78</sup> made disk records from finely powdered horn to which was added a binder such as a natural or artificial resin or casein, and a filler. In order to secure acoustic disks of synthetic resin or cellulose compositions entirely free from solvent, old or newly formed disks are ground up and freed from volatile matter in a vacuum. After this, synthetic resin (or other plasticizing agent) is added and the disks re-formed.<sup>79</sup>

Molded clay, before drying and firing, may be coated with a suspension of colophony (2.5 parts), turpentine (2.5-5 parts) and water (100 parts) with syn-

thetic resin as a binder to secure articles of uniform color.<sup>80</sup> The last stage of firing should be carried out under reducing conditions. So-called "artificial masses" are obtained by treating mud or slime from fresh or salt water (either in its natural moist state or dried in the absence of air) with organic colloidal materials such as natural or synthetic resins.<sup>81</sup> The product is then subjected to the action of hardening or vulcanizing agents. Synthetic resins can also be used as binding agents in the manufacture of refractory articles.<sup>82</sup> Thus, for example, in forming crucibles or muffles, magnesium oxide and crystalline graphite are mixed with a resin (as a binder) and glazing material, and then molded and baked. Molded electrical resistance units can be made from a mixture of graphite, asbestos, clay and a synthetic resin.<sup>83</sup> A material, suggested for the manufacture of buttons, is derived from peat (containing 1 per cent or more of tarry substances) mixed with synthetic resins and powdered blood.<sup>84</sup> Synthetic resins have been applied also in the production of artificial pearls.<sup>85</sup> Moncany<sup>86</sup> developed a moldable plastic material by mixing plaster, fibers and asbestos powder, and incorporating albumin or dextrin. The mixture is molded and baked, then dipped into a bath of water and glycerol, baked again, dipped into a solution of a synthetic resin in alcohol, and baked a third time. The same worker obtained a plastic material from asbestos fiber and paper beaten up with a synthetic resin varnish. Metallic fibers may also be incorporated in the mass.

Synthetic resins may be used as suspension- or dispersion-agents in the removal of coloring matter from waste-paper pulp by agitation with organic solvents.<sup>87</sup>

Rosin employed in the preparation of toilet and medicated soaps can be replaced by an aromatic resinous composition<sup>88</sup> which is made by emulsifying terpenes, synthetic or natural resins and residues from the solvent extraction of flowers ("floral wax"), with glycerol, a solvent such as methyl alcohol or diacetone, and an emulsifier (e.g., ammonium sulphoricinoleate).

Kurz and Albert<sup>89</sup> produced inks for intaglio printing in which pigments are ground in a vehicle prepared as follows: A synthetic resin is dissolved in 96 per cent ethyl alcohol and partly saponified with alkali. Solvents of high-boiling point are added (e.g., methyl cyclohexanone), and the liquid composition is diluted with water.

Alcoholic solutions of natural or synthetic resins can be colored fast to light by basic dyes, such as the triarylmethane dyes, mixed with a small proportion of a strong inorganic or organic acid, an acid salt, or of a nitrate soluble in the varnish.<sup>90</sup> Celluloid, cellulose esters or ethers, or natural and synthetic resins (or their solutions) are also colored by the incorporation of soluble chromium or copper compounds of dyes, particularly of o-hydroxyazo dyes. The materials can

either be kneaded together on rolls, or solutions in organic solvents of the dye and the resin can be blended.<sup>91</sup>

Highly polymerized fatty pitches, such as stearin pitch, which are almost insoluble in organic solvents, can be rendered readily soluble by mixing with soluble resins or resin esters, and subjecting the mixture to hot rolling.<sup>92</sup> Colloidal suspensions of insoluble resins are rendered stable at all concentrations by the addition of a slightly alkaline aqueous solution of an auxiliary colloid such as casein.<sup>93</sup>

Warren<sup>94</sup> has obtained metallic surfaces on resins by coating with, for instance, silver nitrate and powdered silver, subjecting the mixture to the reducing action of formaldehyde and drying. A hard synthetic resin incorporated with bronze powder may be applied as a coating for metal surfaces.<sup>95</sup> Another procedure consists in mixing the resin with water glass, clay or metallic oxides.<sup>96</sup> After applying to the surface, hardening may be effected by heating in the absence of air.

A polishing composition was prepared by Collard<sup>97</sup> as follows: A mixture of fats or oils (3-10 parts), resins (2-8 parts) and synthetic or natural waxes (2-8 parts) is heated to 110-160°C., and a suspension of a fine grit (e.g., kieselguhr) (25-40 parts) in "white spirit" or turpentine (40-60 parts) is added. Other polishing mixtures have been made incorporating powdered ebonite and an incompletely polymerized resin with abrasives.<sup>98</sup>

Beebe and Herlinger<sup>99</sup> produced a light-sensitive photographic coating composition by introducing iodine (dissolved in benzene) into a varnish. The latter contained resins, metal salts capable of combining with the halogen (e.g., lead resinate) and a solvent such as gasoline. Sufficient halogen is introduced to combine with all the salts present, forming metal halides.

A lithographic plate is made by preparing a sheet of metal with a sensitive area to which is applied a lacquer containing a synthetic resin which is substantially insoluble in solvents such as acetone and benzene.<sup>100</sup> Light-sensitive resin layers for preparing etched metal plates for photomechanical printing can be made from solutions consisting of a resin, a chromate, an organic solvent and a base.<sup>101</sup>

According to Tomkins and Woodman,<sup>102</sup> synthetic resins can be used for preserving fruits and vegetables by sealing the cut surfaces of the stalks.

Gas bubbles do not adhere to floats for indicating density when the latter are made of artificial wax and resin. Such floats are made up of equal parts of synthetic resin and synthetic wax with coloring matter and a varying amount of barium sulphate according to the specific gravity desired.<sup>103</sup>

An interesting method for introducing or eliminating substances from a syn-

thetic resin (e.g., the removal of catalysts from plastic materials) depends upon the use of an electric current.<sup>104</sup>

Dauler<sup>106</sup> has described a method for transferring resin from a still to portable containers in such a way that the resin after it has solidified in the container may be broken up readily. In filling the containers (drums), a cylindrical filler core is held in position. The withdrawal of the core from the solidified resin causes cracking and leaves a cavity, both of which facilitate the breaking and removal of the material.

#### RESINS NOT PREVIOUSLY CLASSIFIED

**The Production of Certain Resins and Tars.** The formation of a resin or tar either as a principal or as a secondary reaction product is such a familiar aspect of preparative organic chemistry as to need little introduction. One of the problems of the future in the synthetic resin industry is to determine which of these resinous materials have special properties rendering them adaptable to large-scale application. It is for this reason that many references to resinification have already been included in cases where at the moment no likely application of the product exists. The following pages contain numerous further references of this type which do not come into the classification used in this book.

Phenolphthalein was first prepared by Baeyer<sup>106</sup> in 1871 and was shown several years later to be di-p-dihydroxydiphenylphthalide. When heated to 250-253°C. this compound melts to a clear liquid, and on cooling to 217°C. solidifies to a glass-like mass.<sup>107</sup> The latter appears to be a polymeric form of phenolphthalein. Several interesting resinous derivatives have been made from the phthalide. Maxorov<sup>108</sup> has described a synthetic resin ("Alkalit") obtained by heating the sodium salt of phenolphthalein with toluoyl chloride. When dissolved in oil this gives an almost colorless, transparent, glossy, water-resistant film which is also very resistant to mineral acids and caustic alkalies. Molecular weight determinations<sup>109</sup> of phenolphthalein-o-toluate and m-toluate show that these resins are monomeric. Fused phenolphthalein itself reverts to the crystalline form when used in films. A variety of di-esters and di-ethers of phenolphthalein are known and, with the exception of the di-m-methylbenzyl ether, all exist in a crystalline form and are converted by fusion or by evaporation of their concentrated solutions into colorless resins which crystallize more or less easily on keeping.<sup>110</sup> The ease of conversion to the crystalline state decreases with increasing weight of the chain, and is greater for esters than ethers. The o- and m-tolylates could not be made to crystallize. Their alkali-resistance was greater than that of many natural and synthetic resins.

Other substances allied to phenolphthalein have been found to be amorphous. Thus, catecholsulphonephthalein, described by Wood<sup>111</sup> is an amorphous deep purple solid which is moderately hygroscopic. Phenolphthalein monomethyl ether<sup>112</sup> crystallizes with solvent of crystallization (e.g., one-half a molecule of toluene). After the solvent has been removed by heating, the molten mass solidifies to a

glass-like substance which may be kept for months without crystallizing. Ebert<sup>118</sup> prepared a yellow amorphous phenolphthalein melting above 256°C. by extracting partially purified yellow amorphous phenolphthalein with a solvent such as butyl alcohol.

Terpenes and allied products extracted from various parts of plants such as the wood, leaves and seed have a strong tendency to polymerize or oxidize, yielding gummy and resinous products. Condensation of turpentine with formaldehyde has already been mentioned. (See Chapter 37.)

Grognot<sup>114</sup> surveyed many types of resins, for instance, that from oil of sweet almonds. This resin was obtained by adding, with cooling, sufficient phosphorus pentoxide to the oil to make a viscous syrup and allowing the mixture to stand a few days. When it had become a hard brown mass it was washed with hot water and heated on a water bath to remove excess essential oil. The residue was a brittle mass similar to colophony, and had an empirical formula identical with that of the  $\alpha$ -resin of benzoin. From an alcoholic solution the product could be precipitated by either dilute hydrochloric acid or alcoholic lead acetate solution. Oil of rue yielded a deep brown resin when treated as above.

Oil of anise resinified upon treatment with warm iodic acid, iodine and potash. Oxidation appeared to have occurred, and fusion with potash yielded a small amount of what seemed to be anisic acid.<sup>115</sup>

According to Barth,<sup>116</sup> treatment of oil of turpentine, lavender, or juniper with alcoholic potash, followed by neutralization with dilute sulphuric acid yielded resins which were soluble in ether, similar to colophony and had the formula  $C_{30}H_{50}O_3$ . They were unaffected by further treatment with potash, and were fairly stable to oxidation, though the turpentine resin was converted slowly into fatty acids and a camphoresinic acid analogue. Barth also suggested the possible close relationship of tannins to these resins.

Methyl salicylate (oil of wintergreen) heated in a bomb at 340-350°C. for several hours gives a 60-70 per cent yield of anisole, 15 per cent of phenol and some resin.<sup>117</sup>

Considerable resin formation takes place in the electrochemical oxidation of cymene (a constituent of such essential oils as oil of caraway and lemon) in sulphuric acid-acetone solution.<sup>118</sup> Acetone when heated for 4 hours at 150°C. with zinc and vinyl bromide yields a mixture of butadiene, isoprene, terpenes and polyterpenes.<sup>119</sup>

Many miscellaneous reactions of aromatic and aliphatic compounds lead to tar formation. Complex pitch-like products are obtained by heating diphenyl ether with sodium at 180-200°C.<sup>120</sup> The preparation of dibenzal succinic acid (from benzaldehyde and ethyl succinate) is accompanied by the formation of considerable resin.<sup>121</sup> cis-Decahydronaphthalene-2-carboxylic acid has been stated to be a resin.<sup>122</sup> Oxidation of dimeric triphenylallene with chromic acid gives a product containing 20 per cent of resinous bodies.<sup>123</sup> Phenylbutadiene chloride was found by Muskat and Huggins<sup>124</sup> to polymerize readily on refluxing. The etherification

of ethylene glycol to dioxane in presence of ferric sulphate leads to the formation of much tarry matter.<sup>126</sup> Resin formation has been noticed also in the preparation of quinine-amine phthalate and phthalyl quinine-amine picrate and of other compounds of this group.<sup>126</sup>

Knapp<sup>127</sup> reports that gummy substances are present in the reaction products from o-phthaloyl chloride, benzyl acetate and aluminum chloride, dissolved in carbon disulphide. According to Borsche and Thiele,<sup>128</sup> 3-phenyl-2-pentene-1,5-oxide changes on standing to a white resin. Treatment of heptene or isohexene with perbenzoic acid in ether yields the corresponding oxides which resinify in the presence of zinc chloride.<sup>129</sup> Senderens<sup>130</sup> observed that cyclohexane-1,2-diol is converted into a resin by concentrated sulphuric acid at 110°C. Humic acid, from coal, when treated with 72 per cent sulphuric acid yields 1.8 per cent of an orange-red lacquer-like substance.<sup>131</sup> Guest found that ethylmagnesium iodide reacts with dipropargyl methylene ether, forming a resin insoluble both in ether and in benzene.<sup>132</sup> The thermal decomposition of phenyl fumarate yields first phenyl cinnamate and subsequently stilbene; substituents in the phenyl group lead to formation of resinous products.<sup>133</sup>

A material of a Peru-balsam type is formed by dissolving condensation products from benzoic and cresotic acid derivatives in benzyl benzoate or benzyl alcohol. Thus, powdered sodium cresotate may be added slowly to a cold mixture of benzoyl chloride, benzene and alcohol at 35°C. Calcium carbonate is then added; and after 24 hours the mixture is warmed to 60°C. with addition of alcohol and benzene, and filtered. The solvents are slowly distilled off; and on further heating of the residue at 60°C. for several hours, a soft resin is obtained. It is only slightly volatile in the cold and dissolves in benzyl benzoate and benzyl alcohol.<sup>134</sup> Heating gelatine and creosote to 160-250°C. yields a resin.<sup>135</sup>

Burgess<sup>136</sup> utilized alginic acid, obtained from sea weed, together with paraffin wax in the preparation of a waterproofing material. The process is illustrated by the following example: 300 grams of kelp containing 30 grams of solid is dissolved in 10 cc. of ammonia and 300 cc. of water. Fifteen grams of paraffin wax dissolved in 40 cc. of carbon tetrachloride are then added, together with 3 grams of copper powder. The charge is heated under reflux at 80-90°C. for 15 hours and the product filtered, washed and dried. It may then be extracted with carbon tetrachloride, and the resulting solution evaporated. A calcium alginate may be used also for the manufacture of a non-shatterable glass.<sup>137</sup> Alginate which has been extracted from marine algae has been esterified with a mixture of sulphuric and nitric acids or sulphuric and acetic acids. The resulting nitrate and acetate esters have been suggested as substitutes for nitrocellulose and cellulose acetate.<sup>138</sup> Reaction between carvacrol, malic acid and concentrated sulphuric acid results in resinification.<sup>139a</sup>

An oily liquid product formed in the catalytic reaction between carbon monoxide and hydrogen yields, when condensed with hydrochloric acid, an oil resembling turpentine oil. If zinc chloride is used as the condensing agent, a resinous body is formed in addition to the oil.<sup>139</sup> The initial oily liquid is fractionated before carrying out the condensation reactions. The residue from fractionation may be purified and employed as a resin for lacquers and varnishes.<sup>140</sup>

A lacquer base was prepared by Pierson<sup>141</sup> from gummy leather made by dipping leather in dilute sulphuric acid to which was added urea, ethylene glycol and phenol. Prior to using, the base is dissolved in a mixture of acetone and ethyl acetate. Rosicki<sup>142</sup> heated isosuccinic acid (1 part), resorcinol (2 parts) and sulphuric acid (1 part) at 120-150°C. for 4 hours. The resulting mass was purified by dissolving in alkali and precipitating with acid; it was found to be soluble in alcohol, ether and alkalies. With lead, a red lacquer was produced.

Bills<sup>143</sup> noted when a solution of cholesterol ( $C_{27}H_{46}O$ ) in carbon tetrachloride, benzene or xylene was boiled with previously ignited fuller's earth colored resinous products were formed and adsorbed on the fuller's earth. The resin could be extracted with ether or acetone, and was found to have antirachitic properties. Cholesterol develops chromogenic properties similar to "oxycholesterol" when heated, the product being brown and resinous.<sup>144</sup> A yellow resinous substance may also be extracted from cholesterol which has been exposed to ultraviolet rays.<sup>145</sup>

The monomethyl ether of chitin was obtained in small yields by repeated methylations. When hydrochloric acid was used to swell the chitin before treatment with dimethyl sulphate, a slimy, difficultly filtered mass was secured. On drying, a horn-like product, which could be pulverized, resulted.<sup>146</sup> Acetylation of chitin yielded a dark-brown amorphous acetyl derivative which was soluble in formic acid or 50 per cent resorcinol solution, but insoluble in other organic solvents.<sup>147</sup> When dissolved in nitric acid (sp.gr. 1.5) and the solution diluted with water, a crumbly precipitate of nitrochitin acetate is obtained.

## Chapter 64

# Analytical and Physical Tests of Synthetic Resins

A discussion of the chemistry of synthetic resins and their plastics rightly concentrates on synthesis or production, but some mention should be made of analytical and identification methods, which are usually qualitative. Supplemental investigations may include quantitative measurements such as acid or iodine value, together with physical and electrical tests, but these are most commonly used for control during manufacture.<sup>1</sup>

Despite the relative scarcity, valuable information on specific phases of analysis has been published by Gardner,<sup>2</sup> Van Heuckeroth,<sup>3</sup> and others<sup>4</sup> while Abraham<sup>5</sup> has described the examination of plastic products made with a bituminous base. In certain cases the identification methods used by Ward, Jordan and Fulweiler in studying the composition of gums formed in gas distribution systems may be helpful.<sup>6</sup> However, the scheme of analysis proposed by Bradley<sup>7</sup> is perhaps the most pertinent although he dealt principally with resins in solution.

### ANALYTICAL SCHEME

Systematic grouping of the various synthetic resins is desirable to keep the work from becoming unnecessarily involved. The following arrangement<sup>8</sup> may be of value as, in almost every case, certain possibilities can be eliminated at the outset.

**1. Polybasic Acid Poly-Esters.** These compositions are easily saponifiable, yielding the original constituents or their salts. The saponification number ranges between 200 and 600. The resins are usually soluble with difficulty in petroleum hydrocarbons and ethanol, but ketones, esters or ether-alcohols are more effective. Their density is generally found to be between 1.10 and 1.42, while the refractive index varies from 1.54 to 1.59. Strong fusion will probably give sub-

<sup>1</sup> Detailed descriptions of all analytical methods are obviously precluded in this text, but selection of the most pertinent procedures should be facilitated by the summaries given.

This series of articles discusses the methods which were employed to show that styrene and indene were the parent substances of most of the samples of liquid-phase gum studied.

<sup>7</sup> T. F. Bradley, *Ind. Eng. Chem., Anal. Ed.*, 1931, 3, 304.

<sup>8</sup> T. F. Bradley, *loc. cit.*

limates of phthalic anhydride. In commercial products these resins are most often encountered in nitrocellulose lacquers, enamels, varnishes, paints and primers, frequently in conjunction with aromatic hydrocarbons.\*

**2. Phenol-Aldehyde Condensation Products.** These resins vary from viscous liquids to hard, brittle solids. When modified by large proportions of rosin or fatty acids, they are soluble in petroleum hydrocarbons, and are readily saponified. However, if rosin or fatty acids are not present, saponification is difficult, and aromatic hydrocarbons, ketones and esters are the usual solvents. If unmodified the density will probably lie between 1.20 and 1.28, while the refractive index ranges from 1.62 to 1.69. When heated, a marked odor of phenols, cresols, or formaldehyde may be liberated, and further indications are given by a color reaction in the case of phenols.<sup>10</sup> While resins of this type may be occasionally found in nitrocellulose lacquers, they are more frequently modified and employed in oil varnishes

**3. Cumarone-Indene Polymers.** Unless modified by rosin or fatty acids, these resins are non-saponifiable and are generally insoluble in ethanol. They are, however, soluble in acetone, hydrocarbons, and many esters, and are more easily dissolved in petroleum hydrocarbons than the two groups previously described. The density will probably be between 1.10 to 1.15 but may fall as low as 1.05. Destructive distillation may liberate cumarone and indene, and color reactions are of value. The usual applications of these resins are as bases for spirit varnishes, paints and enamels, especially when maximum alkali-resistance is desired. They may frequently be used with tung oil.<sup>11</sup>

**4. Vinyl Polymers.** In some cases such resins are partially saponifiable and are usually characterized by a water-white or pale straw color. Physically, they may vary from rubbery masses to hard, tough solids which are ordinarily soluble in acetone, ethyl acetate, benzene and toluene, although insoluble in petroleum hydrocarbons. Upon the application of heat, charring takes place, and a distinctive odor is emitted. The density is usually greater than 1.15, and a low refractive index, 1.47 to 1.48, points strongly to the vinyl acetate types. These polymers may also be detected by color reaction. While the resins are seldom utilized with oils in varnishes, they may be found in lacquers with or without nitrocellulose.<sup>12</sup>

**5. Chlorobiphenyls.** Molten caustic can be employed to decompose these resins by fusion, but saponification is difficult unless they are modified by rosin or oils. The solubility in organic solvents, alcohols, ketones, esters and hydrocarbons, is higher than any other group of synthetic resins with the exception of the cyclohexanone-formaldehyde types. At normal temperature, chlorobiphenyls may be found in the form of thin liquids, hard and brittle masses, or semi-crystalline substances which melt readily. The refractive index varies between 1.612 and 1.71 with a density of 1.14 to 1.80. Chlorine may be indicated qualitatively by sodium fusion. Resins of this class are frequently found in either lacquers or varnishes.<sup>13</sup>

\* Representative compounds which are involved in the formation of polybasic acid poly-esters are phthalic anhydride, glycerol, rosin, ethylene or diethylene glycols, pentaerythritol, monohydric alcohols, benzoic acid, succinic acid, maleic acid, malic acid, citric acid, tartaric acid, adipic acid or its higher homologues, other polyhydric alcohols, and higher fatty acids.

<sup>10</sup> Typical constituents of phenol-aldehyde condensation products are phenol, cresols, xylenols, formaldehyde, rosin, glycerol, higher fatty acids, high-boiling tar acids, polyhydric phenols, furfural, acetaldehyde, and ortho- and para-hydroxybiphenyls.

<sup>11</sup> See Chapter 7.

<sup>12</sup> Compounds which are commonly employed in vinyl resin mixtures are vinyl chloride or vinyl acetate polymers, polystyrene, formaldehyde, and cyclohexanone aldehyde.

<sup>13</sup> Chlorinated biphenyl, rosin or rosin ester, and the higher fatty acids are the usual constituents of chlorobiphenyl varnishes and lacquers.

**6. Sulphonamide-Aldehyde Resins.** The color of this group ranges from water-white to pale straw, while the viscosity may be either that of a thick liquid or a semi-crystalline solid. Typical examples of this type have shown a density of 1.35 and a refractive index of 1.596. Sodium fusion may be employed in qualitative tests for sulphur and nitrogen. While the resins are generally soluble in esters, ketones and aromatic hydrocarbons, they are insoluble in ethanol and petroleum hydrocarbons. The condensation product of toluene sulphonamide and formaldehyde may be taken as illustrative of this class.

**7. Urea-Formaldehyde Resins.** The water-white resins may contain urea, thiourea and formaldehyde in combination. As marketed commercially, the products are hard solids, insoluble in water and all common organic solvents; although some of the intermediate condensates may be used as cements or adhesives in aqueous solution. A density approximating 1.48 and a refractive index of 1.66 may be regarded as usual for the harder grades.

**8. Cyclohexanone-Formaldehyde Resins.** Such resins may be distinguished by high solubility in organic solvents, including ethanol, hydrocarbons and oils. They tend to be somewhat hard and brittle and of a pale lemon color. An odor of cyclohexanones or formaldehyde may be detected during fusion. Specimens have given values of 1.207 for density and 1.544 as the refractive index.

In summary, it may be suggested that the resin is synthetic if the density is over 1.15 although it may contain a natural modifying agent. If between 1.10 and 1.15 it is probably a cumarone-indene polymer, shellac or a modified synthetic of another type, and if less than 1.10 it is likely to be either wholly or largely a natural resin. The refractive index and density together give a better indication than either alone, since most synthetic resins are higher in refractive index than the natural materials, with the exception of some cyclohexanone-formaldehyde resins, which are about equal, and some vinyl polymers, especially the acetates, which are lower.<sup>14</sup>

#### PREPARATION OF SAMPLES FOR EXAMINATION

It is, of course, desirable to isolate the resin as far as practicable before attempting analysis. If a commercial product, any pigment present must necessarily be removed either by centrifuging or filtration. Rosin and certain plasticizers, such as phthalates or phosphates, should be extracted with petroleum ether, and the residue, containing most of the synthetic resins, may be subjected to a general examination for appearance, hardness and solubility. Before the qualitative chemical procedure is undertaken, the density<sup>15</sup> and refractive index<sup>16</sup> should be determined.

#### QUALITATIVE TESTS

Qualitative chemical tests may be conducted on these resin residues for halogens, nitrogen and sulphur, using the standard sodium fusion method as described by Mulliken.<sup>17</sup> Behavior of the sample on heating with sodium, or with 50 per cent aqueous sodium hydroxide, is carefully noted, particular attention being paid

<sup>14</sup> Synthetic resins of high refractive index (1.70-1.90) are of value in petrography. See A. E. Alexander, *Ind. Eng. Chem., News Ed.*, 1935, 13, 330.

<sup>15</sup> T. F. Bradley has suggested direct weighing in air and in water for large pieces of resin, the pycnometer for less solid material, and immersion in salt solutions of known density for very small pieces and for films. W. Maas (*Chem. Fabrik*, 1931, 318; *Chem. Abs.*, 1931, 25, 5062) has used tinfoil crucibles and a Westphal balance for bitumens and resins.

<sup>16</sup> The Abbe refractometer may be used, but microscopic methods using reference liquids as given by E. M. Chamot and C. W. Mason (*Handbook of Chemical Microscopy*, J. Wiley & Sons, New York, 1930, 1, 899) are preferred, especially where material is limited.

<sup>17</sup> S. P. Mulliken, *Identification of Pure Chemical Compounds*, 1st Ed., J. Wiley & Sons, New York, 1904, I, 10.

to any characteristic odors (such as acrolein indicative of glycerol or glycerides) which may be evolved. During fusion the odors typical of the various types of synthetic resins are especially strong and may be of assistance in identification. If aldehydes and phenols are present, they may be absorbed in water during destructive distillation of the resin.

Color tests for rosin with acetic anhydride and sulphuric acid, as in the Liebermann-Storch<sup>19</sup> procedure, may be confirmed by the Halphen-Hicks<sup>20</sup> method if desired. Many other color tests for rosin and other natural resins have been described. Brauer<sup>20</sup> and Fonrobert and Pistor<sup>21</sup> used phosphomolybdic acid, phosphotungstic acid or ammonium molybdate; Kämpf<sup>22</sup> has applied dilute copper acetate; Cohen<sup>23</sup> worked with chlorosulphonic acid in chloroform; and Griffon<sup>24</sup> added sulphuric acid to an alcohol solution containing the resin and furfural. Donath<sup>25</sup> suggested cooking the resin with concentrated nitric acid (sp.gr. 1.32-1.33) cooling, diluting and adding an excess of ammonia. Characteristic colors are given by various resins, that for rosin, for example, being orange which slowly changes to a deep brown-red.

Phthalates are identified by their reaction with resorcinol or phenol to give fluorescein or phenolphthalein, respectively.<sup>26</sup> Plasticizers derived from phthalic acid should be previously removed from the sample. The presence of phenols is confirmed by fusing the resin with caustic soda, acidifying, and applying the indophenol test.<sup>27</sup>

Several other tests have been proposed for the identification of phenols. In some instances coupling of the phenolic body with a diazonium compound yields dyes of characteristic colors. Phenol and diazotized p-nitroaniline give a rose-red dye, cresols furnish a rose-pink colored substance, and naphthols blue compounds.<sup>28</sup> Spectroscopic examination of the color is often helpful.<sup>29</sup> Zamparo<sup>30</sup> has described various color reactions given by resorcinol, phloroglucinol and  $\alpha$ - or  $\beta$ -naphthol with hydrogen peroxide in acid (sulphuric or hydrochloric) solutions. Other tests are based on the reaction of phenols with aldehydes, e.g., formaldehyde<sup>31</sup> or vanillin,<sup>32</sup> dihydroxyacetone,<sup>33</sup> and aromatic amines,<sup>34</sup> such as benzidine and toluidine.

<sup>19</sup> The Liebermann test (C. Liebermann, *Ber.*, 1884, 17, 1884) and derived methods are discussed and extended by W. A. LeLande, Jr., *J.A.C.S.*, 1933, 55, 1536. Modifications of the test (particularly for rosin dissolved in linseed oil) are given by J. J. Deeney, *Am. J. Pharm.*, 1932, 104, 282; *Chem. Abs.*, 1932, 26, 2330. For tests on resins and lacquers, see Z. Leppert and Z. Majewska, *Przemysł Chem.*, 1932, 16, 130; *Chem. Abs.*, 1932, 26, 6163; *Farben-Ztg.*, 1932, 38, 154; *Chem. Abs.*, 1933, 27, 615. A. Kraus (*Farben-Ztg.*, 1932, 38, 322; *Chem. Abs.*, 1933, 27, 856) finds distinctive colorations for various types of resins.

## QUANTITATIVE VALUES

Acid numbers<sup>35</sup> and saponification values should be determined. These often indicate the type of resin (under examination) and also the degree of condensation. Titration is usually carried out in a neutral ethyl alcohol or alcohol-benzene solution. Methods employing a two-layer system of benzene-alcohol and saturated aqueous sodium chloride solution are described by Stock<sup>36a</sup> and Coburn.<sup>36</sup> Good end-points are obtained with phenolphthalein, but Weinberger and Gardner<sup>37</sup> have shown that such methods give erroneous results for some resins, particularly shellac. An indirect method for acid number has been developed by Dieterich<sup>38</sup> whereby the resin is dissolved in a standard amount of alkali and then titrated with acid. This procedure is not applicable when easily saponified esters are present, and is unsatisfactory specifically for shellac. It is applicable, however, to many dark-colored resins.

One of the most accurate methods for the determination of acid numbers is electrometric or potentiometric titration and a type of cell for this purpose has been developed by LaMer and Downes.<sup>39</sup> However, no standard procedure has as yet been developed which is to be recommended for all resins.

According to Ulrich,<sup>40</sup> phthalic acid may be determined in the following manner: The sample (15-20 g.) is refluxed with benzene and excess 1*N* alcoholic potassium hydroxide for 4 hours. The mixture is then diluted with water, and alcohol and benzene removed by distillation. Any unsaponifiable matter is extracted with ether. The aqueous alkaline solution is acidified with hydrochloric acid and monocarboxylic acids separated with benzene (in which they are soluble). The residue is made just alkaline with sodium hydroxide and lead acetate added. The precipitate of lead phthalate is washed with dilute acetic acid and converted to lead sulphate.

Saponification numbers can be determined by heating a weighed sample of resin with 0.5*N* or 1*N* sodium hydroxide in methanol and titrating the excess alkali.<sup>41</sup> Equal volumes of benzene and normal alcoholic caustic may be employed when the resin is difficultly soluble.<sup>42</sup> The usual indicator is phenolphthalein, though others may be employed. Salvaterra<sup>43</sup> has proposed alkali blue as an indicator in titrating resins which give dark colored solutions.

In cases of high saponification numbers it may be desirable to treat enough material so that the acids can be identified, since a number over 200 is a strong indication of esters of the polybasic acid type. Wolff<sup>44</sup> has used a variation of the Twitchell method to separate oxidized fatty acids and resin acids by means of diethyl sulphate. Acid, saponification and iodine numbers may be determined on

<sup>35</sup> A review of acid number determinations has been given by H. Weinberger and W. H. Gardner (*Ind. Eng. Chem., Anal. Ed.*, 1933, 5, 267). E. W. Diener and S. Werthan (*Proc. Am. Soc. Testing Materials*, 1908, 98; *Chem. Abs.*, 1930, 24, 3916) give a method for use on driers and soaps when metals are present. L. Hambrook (*J.S.C.I.*, 1927, 5, 147) has cited an example of the use of acid numbers as applied to copal varnish.

the separated material. The Wijs method<sup>45</sup> has been recommended for iodine number, both on the acids and on the original resin.

### SPECIALIZED EXAMINATIONS

Various other constants, such as ester value, Helmer's number, acetyl value, Maumené number, Reichert and Reichert-Meissel value and hydroxyl number<sup>46</sup> have been used in the identification of oils, fats and waxes and some may occasionally be applied advantageously to resins. Cumaron-indene resins may be identified by the methods of Wolff as modified and extended by Ellis.<sup>47</sup>

Special chemical tests are made on resins and resin products to determine certain definite properties. The solubility of many commercial resins in various solvents has been reported by Van Heuckeroth<sup>48</sup> while Ostwald and Gamm<sup>49</sup> studied the solubilities of both natural and synthetic resins in sodium hydroxide solutions.

Certain resins may be identified according to a method known as capillary analysis developed by Stock<sup>50</sup> and described by Fonrobert and Pistor.<sup>51</sup> It is based on the observation that pieces of filter paper, partially immersed in resin solutions for periods up to 24 hours, show variations in capillary rise, color, opacity and general appearance which, under controlled conditions, may be sufficiently characteristic for classification.

Analyses may be conducted on resin products for special information. For example, resins can be ashed and the residue examined for traces of lime, soda, or other material which might have been used as a catalyst. Confirmatory tests may be applied for lubricants such as stearic acid, mineral oil or carnauba wax. Mineral fillers are readily determined, in most cases both qualitatively and quantitatively, and in some cases a fineness test on the filler, by screen analysis or microscopic examination, is worth while. Organic or carbonaceous fillers such as wood flour, cotton flock, carbon black, graphite, or lampblack are more difficult, as they do not show up on ashing the sample. Microscopic examination of a broken surface and of the ash will be helpful in some instances. Bone black in appreciable quantity can be detected by an analysis of the ash for phosphate, which is especially significant if calcium is also found to be present.

Plasticizers may be separated and determined in the case of coating materials tested before application and sometimes in thermoplastic preparations, such as cellulose-ester-base plastics, vinyl and styrene resins, shellac and other natural resins. In this respect, inspections of articles molded from reactive resins are difficult, but unreacted molding powders should yield some information. Ryan

<sup>46</sup> W. L. Roberts and H. A. Schuette, *Ind. Eng. Chem., Anal. Ed.*, 1932, 4, 257.

<sup>47</sup> A rapid method for determining the presence of cumaron is by a color reaction with bromine. Cumaron resins will give a permanently red color when treated with bromine in a solution of dry chloroform in the presence of glacial acetic acid. Pontianac will color the solution yellow though there may be a slight red tint when the bromine is first added. It is therefore advisable to check the color after the solution has stood for some time, usually 24 hours. Often one hour's time is sufficient to develop the color definitely except when Pontianac resin is present in large proportions, and in this case it is preferable to resort to the destructive distillation of the resin with the subsequent identification of cumaron and indene in the distillate as given above.

The test is carried out as follows: 1 cc. of a 10 per cent solution of the resin in chloroform is diluted with 6 cc. of chloroform and 1 cc. of glacial acetic acid is added. The solution is then shaken or stirred and 1 cc. of a 10 per cent solution of bromine in chloroform is added, the solution again shaken or stirred, the container corked and allowed to stand, the presence of cumaron resin being indicated by the permanent red color of the solution.

The foregoing method of separating and identifying cumaron resin was developed and successfully used in the author's laboratory.

and Watkins<sup>55</sup> have given procedures for the determination of plasticizers in cellulose ester compositions.

Solvents for resins and cellulose derivatives are becoming so numerous and complex that they can no longer be detected by their odor and, perhaps, boiling range. A recognized procedure, moreover, is not available and identification has to be made by fractional distillation, boiling range, density, and optical properties, confirmed by special tests if necessary. Jordan<sup>56</sup> has given much information which is of value in the examination of both solvents and plasticizers. Gardner<sup>57</sup> and Durrans<sup>58</sup> also collected considerable data on both subjects.<sup>59</sup>

#### APPEARANCE, COLOR AND OPTICAL PROPERTIES OF RESINS

Bradley<sup>57</sup> has based his scheme of analysis on the density and refractive index of the various resins, but certain investigators have taken advantage of other optical properties for identification. Stock<sup>60</sup> and Nicolardot and Coffignier<sup>61</sup> have reported that they are able to distinguish various resins and also show why some gums are brittle merely by visual examination under the microscope. Adulteration and uniformity of blended products may also be observed. Roninger<sup>62</sup> described microscopic methods employed for rubber, but requiring only little variation for use on resins or their products.

Any polarizing action of the resin may of course be observed between crossed Nicol prisms in a microscope equipped for this purpose and may be conveniently investigated when the refractive index is measured.

The color and color-stability is of importance, especially in the field of coatings and light-colored molded and turnery products. Van Heuckeroth<sup>63</sup> has reported initial color estimates on resins used in coatings, and also stated the extent to which the film darkened on exposure. A number of instruments are now available which will determine and record the color of opaque objects as a graph of the spectrum showing the intensity of the light of each different color. Investigations of resins are usually made by transmitted light, however, and are not so complete. As a basis of comparison, Fonrobert<sup>62</sup> suggested a solution of iodine in potassium iodide and gave numerical values corresponding to the rosin color standards.<sup>63</sup> Albert<sup>64</sup> advocated solutions of potassium chromate or dichromate.

The value of the refractive index as a means of classification has been pointed out, but considerable care must be taken in making observations as the results may be influenced by particle size, reflectivity and other factors, including water.<sup>65</sup> Plonait<sup>66</sup> employed optical rotation of solutions to distinguish real amber from copal resins and to detect adulterations. Double refraction due to the "streaming" effect of rod-like molecules has been noted in colloidal solutions of many highly

polymerized compounds by Signer.<sup>67</sup> X-Rays have been used extensively<sup>68</sup> in the study of the structure of both natural and artificially polymerized colloids<sup>69</sup> and Ott<sup>70</sup> has reported the degree of polymerization of certain aldehydes by means of this type of measurement.

Phenol-formaldehyde resins are transparent to ultraviolet rays to a depth of 0.7 mm. with resultant yellowing, according to Risler.<sup>71</sup> Clement, Riviere and Beck<sup>72</sup> found that pure nitrocellulose is not darkened by ultraviolet light, but that traces of phenolic compounds do bring about this change. Sugimoto and Kasai<sup>73</sup> studied light absorption and transmission by phenol-formaldehyde resins in both visible and ultraviolet light. When no condensing agent was used, broad absorption bands were produced in the ultraviolet range. These were shifted by the addition of various amounts of a transparent lemon-yellow resinous decomposition product of hexamethylenetetraminetriphenol, the latter being formed when ammonia was used as a condensation agent in the original reaction.

Distinguishing fluorescent effects have been noted when resins are exposed to ultraviolet rays. Wolff and Toeldte<sup>74</sup> have given tables showing the characteristic color and appearance of the fluorescence when resins were examined in the form of lumps, powder or solutions in butyl acetate.<sup>75</sup> Danckwortt<sup>76</sup> has discussed the use of ultraviolet fluorescence in the examination of resins and also solvents, oils, various pigments and driers.

#### HEATING AND TEMPERATURE EFFECTS ON RESINS

The colloidal nature of both synthetic and natural resins is apparent from their behavior when heated, as they usually do not exhibit a clearly defined melting point.<sup>77</sup> The properties change gradually, sometimes over a very wide range of temperature, while the specific heats are complicated by heats of transformation from one form to another which furthermore may occur at different points on heating and on cooling. In the case of certain reactive resins these changes are not reversible, as curing may take place below the melting point of the resin. Plasticizers or solvents may affect softening points and not the reaction temperatures, while hardening agents or condensing agents often alter the reaction temperature alone.

Many different methods have been proposed for the determination of the softening and melting points of resins and similar materials.<sup>78</sup> Van Heuckeroth<sup>79</sup>

<sup>75</sup> Albertol resins show the most intense color (blue) while ester gum, lime-hardened rosin and Congo copal in decreasing intensity show blue. G. Kostka (*Chem. Ztg.*, 1920, 53, 117, 138; *Chem. Abs.*, 1920, 23, 2308) has reported that phenol-formaldehyde resins do not fluoresce although they absorb the ultraviolet light. Amber is indicated by a yellow-green to blue-white color, but the pressed and cloudy forms are less active. Urea-formaldehyde resins exhibit a faint fluorescence, casein and cellulose products show blue or blue-white, and all are easily distinguished from amber. Filters are available which pass the ultraviolet but restrict all other rays, including visible light.

<sup>76</sup> P. W. Danckwortt, *Farben-Chem.*, 1932, 3, 140; *Brit. Chem. Abs. B*, 1932, 613.

<sup>77</sup> Crystalloids absorb heat at a more or less uniform rate corresponding to the specific heat of the solid. Then melting occurs, and the heat of fusion is absorbed at a temperature which, for pure substances, does not vary a fraction of a degree. When all the solid has melted more heat raises the temperature of the liquid at a new rate corresponding to the different and usually higher specific heat of the liquid. Temperatures are sharp and heat effects may readily be measured.

<sup>78</sup> H. A. Gardner, "Physical and Chemical Examination of Paints, Varnish and Lacquers," 5th Ed., Inst. Paint & Varnish Research, Washington, D. C. H. Abraham, "Asphalt and Allied Substances," 2nd Ed., D. Van Nostrand Co., New York, 1920.

<sup>79</sup> A. W. Van Heuckeroth, *Circ., Amer. Paint & Varnish Mfrs. Assn.*, 1930, 369, 354.

has compiled the softening points of commercial soluble synthetic resins available in the United States. Nagel<sup>60</sup> has reported values for German resins using a modification of the Krämer-Sarnow mercury method. In the Durrans procedure,<sup>61</sup> 3 g. of the resin (in a test tube) are carefully melted, and the mass allowed to cool and harden. Fifty g. of mercury are placed on the solid and the container and contents slowly heated (2°C. per min.) The temperature at which the resin floats on the mercury is taken as the melting point. This method has been modified by Rangaswami<sup>62</sup> for use with small amounts (0.2 g.) of material. While no system has been accepted for general use, the American Society for Testing Materials has issued tentative specifications for the determination of the softening and fluid temperatures of rosin.<sup>63</sup>

Melting points have been measured by Dennis and Shelton<sup>64</sup> using a long copper bar 1½" square, heated electrically at one end so that the temperature varies uniformly over the length of the piece. The material is placed on the top surface as a long trail of powder, and the degree of heat where melting is observed may be found by a sliding thermocouple. This device is well suited for work with resins, as the sample can be exposed simultaneously to a range of temperatures and the melting points or ranges noted. The effect of time on contact may also be found, and, with reactive resins, the curing may be observed, although the time is not comparable to that required when pressure is exerted on the specimen.

### VISCOSITY OF RESINS

The viscosity of resins is of practical importance in connection with coating and impregnating solutions.<sup>65</sup> Several of the viscometers<sup>66</sup> developed primarily for the oil industry may be adapted to this work but comparative tests may be made with a pipette, or bubble tubes. Van Heuckeroth<sup>67</sup> has given the viscosity ranges of many varnish resins and Keyssner<sup>68</sup> has described the effect of the chemical constitution of the solvent on the viscosity of resin solutions.

### PHYSICAL AND ELECTRICAL TESTS ON RESINS

For purposes of identification, the physical and electrical characteristics of resins are of little value, although they have considerable significance from a commercial standpoint. However, in cases where this information may be required for the proper control of production, the apparatus and procedure will generally be found to be identical with those described for molding and coating preparations.<sup>69</sup>

## Chapter 65

### Preparation of Hot-Molding Compositions

Synthetic resins are widely used as binders for molding compositions which are shaped under heat and pressure into a great variety of products. This application is an art in itself, and, as a result of continuing development is attracting increasing attention from designers, engineers, and artists, as well as from manufacturers in many fields.

Variations in molding properties and requirements, and the almost infinite number of shapes and applications of molded pieces, make it impossible to lay down fixed rules for manufacture, design of molds or manner of molding. Each resin, molding composition and product presents in some respects a distinct and separate problem, but information concerning present methods should be helpful in meeting new situations.

#### USES

The applications of thermoplastic molded products cover a large and diverse field. Compositions containing natural resins, such as shellac, are limited because of their poor resistance to heat but find extensive use in phonograph records and other articles that are not required to withstand elevated temperatures. Synthetic thermoplastic substances which are tough and have a higher softening point, for example the vinyl resins and certain resinous materials derived from rubber, are being used for many purposes, since they will stand more heat, but for extreme thermal resistance the thermosetting and cold-molded compositions are required.

Many thermosetting synthetic resins have been developed in recent years, typical of which are the urea resins, which are particularly useful because they combine light-stability with high mechanical strength and other physical properties required in this type of material. The alkyd resins are likewise being used in a number of special applications. There has been a tendency to employ various resins in the production of certain articles formerly made from rubber.<sup>1</sup>

It is often possible to substitute molded parts for metal, eliminating elaborate machine operations, with a consequent saving in cost and improvement in both appearance and service of the product. Not only may these plastic compositions be shaped as required,<sup>2</sup> with holes, screw threads, figures, letters and designs, but pieces of metal, rubber or other material may be wholly or partially embedded in the article at the time of molding, according to the requirements. The molded piece can also be obtained with a high surface luster that needs little or no finishing treatment, allowing the article to be completed in all respects in a single molding operation. The process adapts itself readily to mass production at low unit cost by the use of multiple-cavity molds and modern presses.

The electrical properties of most resinous compositions are excellent, so that

<sup>1</sup> F. Cellin, *Metallbörse*, 1935, 24, 1417, 1482; *Chem. Abs.*, 1935, 29, 2026.

<sup>2</sup> J. Scheiber and K. Sändig ("Artificial Resins," Trans. by Fyleman, Pitman, London, 1931, 362) have given a list of over 200 articles made from phenol-formaldehyde resins. The products range from acid-proof coatings to x-ray tubes, and include such diverse items as pistons, necklaces, sword handles, banjo frames and pipe line. The list was furnished by Bakelite G.m.b.H.

molded articles may be advantageously employed in electrical apparatus and instruments of many types.<sup>a</sup> Metal inserts may serve as contacts or conductors as well as for purely mechanical purposes. Molding compositions which transmit electricity to some extent may result when large proportions of graphite, copper powder or other powdered conductors are incorporated. By proper proportioning, such mixtures may be used as resistors, for example in radio work.

The ability of some molding materials to become quite plastic and flow readily under pressure when heated permits the forming of articles with thin strong walls, an important advantage in many diversified uses particularly where light weight in relation to size is a factor. Products molded with heat-resistant compositions will retain their shape and color at elevated temperatures and find many applications in connection with electrical heating appliances.

These preparations are likewise adapted for ornamental and decorative purposes, because of the lustrous finish obtained by the use of a highly polished mold. Smokers' articles, boudoir and toilet accessories, boxes and bottle closures may be taken as examples. Compositions of either uniform or mottled colors afford a wide choice for artistic development.

### MOLDING PROCESSES AND COMPOSITIONS

In the actual molding operation the composition of resin and non-resinous fillers is given the desired form by use of some kind of a mold together with heat, pressure, chemical reaction, evaporation, cooling, or some combination of these.<sup>4</sup> The permanently thermoplastic materials are heated, placed in the mold under pressure and hardened by cooling. Necessarily, thermoreactive resins are thermoplastic in the first stages of pressing and are given the required shape while in this state, followed by hardening due to chemical reaction, usually produced by further heating in the mold, so that the shaped article may be removed from the press with little or no cooling. These compositions for thermoplastic and for thermoreactive molding are mixtures of the desired natural or synthetic resins with fibrous materials, powdered fillers, dyes, pigments, lubricants and sometimes plasticizers. They are hard at ordinary temperatures, and may be used in the form of sheets, powder or compressed pellets or pills. In cold molding, a soft, powdered material is shaped at room temperature under very high pressures to form an article which must then be hardened outside of the mold by evaporation of any solvent and baking at relatively high heat.<sup>5</sup>

### RANGE OF PROPERTIES AVAILABLE

The increasing demands of industry for molded articles to meet specific needs has made available a number of compositions possessing various combinations of properties.<sup>6</sup> These characteristics may be varied within certain limits and can be utilized to advantage in meeting the particular requirements imposed by the shape and size of the piece and the service demanded of it.

The properties of moldings made with the same composition vary so widely as to prevent the presentation of precise data which will be generally applicable. For example, the length of time that a particular piece made with a reactive binder is heated under pressure is of fundamental importance in fixing its char-

<sup>a</sup> L. E. Barringer, *Gen. Elec. Rev.*, 1927, 30, 387. W. W. Werring, *Bell. Lab. Record*, 1931, 9, 470; *Chem. Abs.*, 1931, 25, 4071. J. A. Crabtree, *British P.* 344,422, 1929; *Chem. Abs.*, 1932, 26, 3312.

<sup>4</sup> A large number of variations are possible when so many factors are involved but the more important methods of molding actually in use are described in Chapter 68.

<sup>5</sup> The subject of cold molding is treated in Chapter 66.

<sup>6</sup> K. Ripper, *Plastics*, 1930, 6, 384; 402; *Chem. Abs.*, 1930, 24, 4342.

acteristics. From the standpoint of production, the period of cure influences the proper ejection of the molded article from the mold, and subsequent satisfactory service is likewise to a great extent dependent upon correct treatment in this stage. Under-cured pieces, while seemingly perfect on the surface, may distort with temperature changes, are susceptible to atmospheric conditions and are more readily affected by moisture and solvents than properly finished products.

Molding compositions containing reactive resinous binders may be so processed by the manufacturer as to have different degrees of plasticity and are usually available in three grades, soft, medium and hard. This allows the choice of the type giving the correct flow under the particular conditions employed, resulting in more uniform cure and better quality. Mixtures or blends of different hardness may be used if closer regulation is desired.

In addition to their value as electrical insulators and their ability to resist high temperatures, other properties of thermosetting compositions have promoted their extensive use in articles which must be unaffected by weather conditions, moisture, chemicals, acid fumes and solvents. The molded material can be machined and finished to a smooth surface, or it may be drilled and tapped, forming a substantial thread. A few unusual applications will illustrate the variety of uses of the products. Storage battery boxes may be molded in one operation,<sup>7</sup> scale cases<sup>8</sup> and radio cabinets may be made in complicated and attractive shapes, sizes and colors. Balance weights show small change due to wear because of the low specific gravity of the material as compared to metal. Water faucets<sup>9</sup> are now molded and, of course, are free from corrosion.

The unusual resistance to wear is responsible for a great number of applications as in floor coverings,<sup>10</sup> brake lining compositions<sup>11</sup> and even bearings; also the notable waterproofing action is of value in general service as well as for electrical equipment.

Various methods of decoration have been described which are particularly adapted to synthetic plastic materials;<sup>12</sup> for example, openwork patterns<sup>13</sup> or metal powder<sup>14</sup> may be molded into the surface of an article.

**Color.** Synthetic resin products are made in all colors,<sup>15</sup> but not every type of composition affords variety in this respect. Molding materials containing urea resins as binders can be secured in practically all colors from black to white with perfect stability to light. Such preparations are generally molded at a slightly lower temperature than those using a phenolic resin binder. Translucent articles in various shades can also be obtained from urea resins and these are being used to a considerable extent in commercial art.

The alkyd resins are also available in the lighter colors. However, they have the disadvantage of requiring a much longer curing time and their application is therefore confined largely to casting rather than rapid press molding.

Plastic phenolic compositions are made in several colors, black and brown being most widely used. Red, green and blue are also prepared but pastel shades and white are difficult to produce and maintain because of the effect of light on

the phenolic resin. Excessive temperature or length of heating in manufacture will also cause darkening.<sup>10</sup>

For many purposes, such as containers for toilet preparations and foods, it is of the utmost importance that the molded product retain its color without leaching or bleeding, to avoid discoloration of the contents. As such articles are likely

*Courtesy Bakelite Corp.*

FIG. 168.—Matching Colors of Polystyrene on Laboratory Rolls.

to be used in contact with many substances whose compositions are unpredictable and often a trade secret, it is impossible to give any fixed rule of color selection that will cover all contingencies. It is advisable when there is any doubt regarding the effect of a substance on the color selected, to make an actual test before starting a production schedule.

Cast phenolic resins are available in great variety ranging from opaque to translucent or transparent. They are somewhat susceptible to light, but are finding wide use for cutlery handles, jewelry, clock cases, lamps, and many other small ornamental objects.

<sup>10</sup> R. Jones, *British Plastics*, 1933, 4, 538; 5, 20. This discusses dyes and pigments, and discoloring of both resins and colors under various conditions.

The vinyl and styrene resins are also used in color work to advantage as they are transparent or translucent and do not darken when exposed to light. Numerous colored objects made of vinyl resin compositions have been described by Davidson and McClure,<sup>17</sup> including wall panels, cosmetic jars, dentures, phonograph records<sup>18</sup> and automobile steering wheels. See Fig. 168.

**Surface Finish.** The smooth, lustrous surface on a molded article is primarily dependent on the finish of the mold. Most of the molded products that are used for artistic purposes are hot-pressed and the high initial luster is permanently retained by high grade material of this type. Gloss may be further increased by a light burnishing, as with a soft rag buffing wheel, but care is required that the surface resin is not removed from the article by this operation.

The finish may, however, be injured by molding conditions. Excessive temperature is apt to cause waviness, and too rapid closing of the mold before the material is sufficiently plastic may result in flow marks. Delay in closing a hot mold after a reactive composition has been placed in it will produce dull lusterless patches as a result of the reaction of the resinous binder without pressure.

Insulators formed in a highly polished mold will have better permanent electrical surface resistivity than those made in a poorly polished mold, as a film of dirt or moisture will form more readily on a dull or uneven area.

The proportion of resinous binder in the composition is also an important factor in obtaining a lustrous finish. High polish is secured by forming a surface layer of practically clear resin produced by the pressure of molding which compacts the mass and forces excess binder to the outside. Preparations deficient in resin will produce unattractive pieces.

**Mechanical Strength.** The mechanical strength of molded products is of the utmost importance in a majority of applications, the main factor being the ability to resist shock. The strength of most molded compositions against impact lies partly in the quantity and fibrous nature of the filler. Examples of manufacturing conditions which may reduce the mechanical strength of an otherwise satisfactory article are a temperature too low to flux the binder properly, pressure insufficient to compact the material, the use of a composition which has too little plasticity to fill the mold completely, and charging too small an amount of material when employing a semi-positive mold.

For most purposes, preparations containing wood flour filler have sufficient strength. Materials that have a relatively high resistance to shock are also available and are composed of a long-fibrous filler or small pieces of fabric combined with a resinous binder. Long-fiber asbestos is used particularly when the molded article is required to resist the disintegrating effect of high temperature or acids.

**Heat Resistance.** Heat resistance<sup>19</sup> of molded products is, for many purposes, quite as important as mechanical strength and always requires consideration. Articles that will not withstand a temperature of 100°F. (38°C.) without deformation are suitable only for use in temperate climates and care is needed to see that they are not exposed to direct sunlight. Compositions containing a permanently fusible, low-melting binder, shellac for instance, will warp and become distorted by the heat of the sun or even at moderate room temperatures when subjected to some pressure. Thermoplastic materials of higher melting point such as vinyl or styrene resins and certain resins

<sup>17</sup> J. G. Davidson and H. B. McClure, *Ind. Eng. Chem.*, 1933, 25, 645; *Plastic Products*, 1933, 9, 143.

<sup>18</sup> H. Chase, *British Plastics*, 1933, 4, 446. A thermoplastic compound made from rubber is available from deep to pastel shades and may be transparent or opaque. The resin itself is a light amber color and is not affected by light.

<sup>19</sup> For method of measurement see Chapter 69.

derived from rubber, will stand considerable exposure to heat especially when highly filled, but molding compositions containing a reactive resin as a binder, when properly treated for conversion to the infusible state, are unaffected by much higher temperatures. Phenol-formaldehyde moldings containing wood fillers are not damaged by a continuous temperature of 250°F. (125°C.) under conditions of normal humidity, while products containing an asbestos filler may be heat-resistant for short periods up to 570°F. (300°C.). Some of the latter have been satisfactorily used in contact with moisture in valve discs for steam lines and in acid-resistant ware for chemical plant equipment.

**Electrical Properties.** The American Society for Testing Materials and the National Bureau of Standards have made careful studies of the dielectric and mechanical properties of molded materials,<sup>20</sup> and methods of evaluation have been developed. As large quantities of molded products are used in electrical appliances and for insulation, the manufacturers of these compositions carefully guard against any reduction in dielectric value, avoiding contamination from metal or other conductive materials. Large quantities of such carefully made moldings have been satisfactorily employed for high-tension work.

These compositions are likewise well suited for use with the high-frequency currents encountered in the radio field. Groff has developed a preparation said to be highly resistant to surface leakage or arcing when properly molded.<sup>21</sup>

**Machining Characteristics.** In spite of the fact that synthetic plastic materials can be molded or cast in almost any form desired, there is considerable demand for products made by machining. The cast resins may be worked either automatically or by hand to produce finished articles from the rough shapes.

Molded articles usually are so designed that little machine work is required, unless it is on metal inserts as in the case of automobile distributor caps. The "flash" or overflow should not require any tooling for removal unless it be with a file or a punch. Occasionally, however, it is found more economical to drill or tap holes which would otherwise require a very complicated mold or press arrangement.

Laminated products made in sheet form are frequently punched, milled or otherwise fabricated to produce gears, wheels, or insulation. In general, standard tools may be used on all molded products, and machine shop practice is somewhat similar to that used for working brass.<sup>22</sup> Cutting edges dull very quickly, however, probably because the poor heat conductivity of the material creates unusually high temperatures, destroying the temper of the instruments.

Specially designed tools have been made for use on Bakelite and are recommended by some manufacturers when high-speed production is required. Tungsten carbide or diamond-pointed<sup>23</sup> implements have also been employed.

Punching dies are very similar to those used for metal, except that smaller clearance is required. The holes in the stripper plate should also be a close fit around the punch to prevent lifting the edge.

The sheeting or shaping operation, long used in cutting celluloid, has been applied to cast resins.<sup>24, 25</sup> When formed in lead molds they have been sliced into sheets by cutting both the mold and the resin at the same time.<sup>26</sup>

## BINDERS

Binders used in hot-molding compositions divide themselves naturally into two groups, requiring different treatment during pressing and yielding products of distinct characteristics. The first of these groups, which is also the older in point of industrial application, embraces resinous materials that remain permanently fusible, and includes the natural resins of which shellac is the most important example. The members of the second group have the property of undergoing a polymerization, or other chemical reaction, under heat which renders them permanently infusible after treatment. These are typified by the phenol-aldehyde and urea-aldehyde resins. Naturally, these two groups are not definitely defined and clearly differentiated. Rather they tend gradually to merge into each other with the dividing line determined by the definition of the term infusible. Many materials whose temperature of flow or fusion is increased by heat treatment still remain sufficiently fusible to put them into the first class under one set of conditions while permitting them to be considered as infusible under another.

Molding procedure should be adapted to this peculiarity of the resinous binder, which must in turn be adapted to the service required of the finished product.

**Fusible Binders.** Binders of this type, which include the natural resins, shellac, copal and rosin, were the original bases of molding compositions and one can trace the primary motive which led to the development of synthetic resins in an effort to improve shellac molding materials. In such a history, there has been a gradual development in the technique of handling fusible preparations to meet changing requirements. Shellac, for instance, is easily formed to produce articles of considerable toughness and a good surface finish, and has been extensively used for purposes where its relatively low softening point was not detrimental. The applications were many and as demand grew, particularly in the manufacture of phonograph records, the price of shellac naturally rose and encouraged the use of cheaper materials to extend or replace it.<sup>27</sup> Various natural resins, treated rosin and asphaltic compounds, as well as mixtures of these, came into prominence to take the place of the more expensive shellac, and finally a number of synthetic resins, cumarone, phenol-sulphur chloride and others of the fusible type have invaded this field. Cumarone resin, to which linseed oil has been added to overcome brittleness, and, more recently, vinylite resins have found some application in sound records. However, natural resins and mixtures of these with asphaltic compounds continue to dominate the field, despite threats from fusible synthetic types. It is doubtful if this condition could long continue should a fusible synthetic resin possessing the hardness and toughness of shellac, but with a higher softening point, be made cheaply available.

**Reactive Binders.** Reactive, thermosetting synthetic resins include the phenol-aldehyde and the urea-aldehyde reaction products as the most widely employed binders for molding compositions. Other resins are principally used for special purposes or to obtain certain desired properties. The resin binder for hot molding should have a relatively sharp melting point and be fairly liquid at the operating temperature to enable it to cover the fibrous filler properly and yield a sharp impression. Its fluidity, however, should not be so extreme as to permit it to separate from the filler and exude from the mold when pressed. It should be mobile enough to fill the cavity completely without requiring excessive pressure and at the same time sufficiently viscous to remain uniformly mixed with the filler.

<sup>27</sup> See description of phonograph record manufacture, in Chapter 68.

Resinous binders that soften but do not flow may be employed with an added flux or plasticizer. Resins quickly rendered infusible by heat are especially desirable from a production standpoint, but frequently require the addition of a flux to increase flow and permit their use in intricately shaped molds. Rapid hardening or fast cure allows molded articles to be made quickly by hot-pressing, often without the necessity of cooling the mold to avoid adhesion of the piece during ejection.

The time required for heat-treating must be fixed in proper relation to the type of composition employed and the shape and size of the piece to be made if uniformity of product is to be secured. Articles having thick walls or cross sections require a longer heating than thin-walled pieces, to allow the interior of the mass to be hardened properly. Undercured pieces may cause trouble in molding and never give the maximum of service.

The odor of a molding composition is usually that of the binder and, while normally this is not an important consideration, it cannot be entirely overlooked. The heat of molding temporarily accentuates this, but after cooling, the odor should not be so pronounced as to be objectionable under ordinary conditions. At the higher temperatures, the binder must neither liberate appreciable amounts of gas (creating an internal pressure in the mold and resulting in blistering of the finished piece) nor undergo decomposition (thereby effecting staining of or sticking to the mold).

Weaknesses in binders can often be partially offset by the proper choice of fillers or the addition of other substances to the composition. The mixing of binders that have different properties is frequently advantageous. No composition is ideal in every respect and the investigator in this field will find many opportunities for research.

#### FILLERS

Upon the proper selection and use of the filler, no less than of the binder, depend the qualities of finished molded products. When properly selected and blended with the binder, fillers are essential constituents of the molding composition, contributing largely to the mechanical strength and other valuable properties of the articles made from it. The choice of an appropriate filler must be based upon several factors affecting the final composition. Resins alone, when pressed or cast and cooled, develop internal strains and stresses resulting from contraction on cooling, which may lead to cracking. The effect of shrinkage can only be prevented by lengthy tempering or annealing of the piece through long heating and slow cooling. When fillers are added before molding, they perform the important function of minimizing this shrinkage and of offsetting its effect on the article. Fibrous materials are particularly useful in this way and in addition they improve the shock resistance and mechanical strength of the final product. While it is true that the cost of fillers on a volume basis is generally less than that of the resinous binder which holds them together, fillers should in no wise be considered adulterants, for choice based on this view is sure to reduce the value of the product. Many valuable properties of molded articles, in addition to strength and shrinkage, depend on the selection of a filler and a binder adapted to each other and to the problem in hand.

**Wood Flour.** Perhaps the most universally used filler in molding compositions of the thermosetting type is finely pulverized wood commercially known as wood flour. Although commonly termed a filler, it is likewise a reinforcing ingredient as it improves the shock resistance, yielding a tougher product whereas

the resin alone would tend to be fragile. It also contributes to the flowing properties of the composition. Wood flour is made from various species of trees, spruce, fir and white pine being used both in this country and Europe because they yield the better grades of flour of light color. A relatively high content of natural gum, as in long-leaf yellow pine, is undesirable, since compositions containing it require special treatment to counteract the effect of the natural resin. The characteristics of wood flour<sup>29</sup> to be considered are particle size and shape, bulk, natural gum content and color. Upon examination under a microscope the particles of the stock should show a fibrous structure and be fairly uniform in size. The material should be free from foreign substances, particularly those of a metallic or abrasive nature which might affect the dielectric properties of the product or injure the mold. Customarily about eighty per cent should pass through an 80 mesh screen. The moisture content, an important factor in dielectric strength, is determined<sup>30</sup> by loss in weight on heating at 105°C. for 24 hours and should not be over 5 or 6 per cent. The impregnation and mixing of wood flour with a resinous binder has a tendency to seal in any moisture that may be present in the filler, and, to obtain maximum insulating properties, the former should be thoroughly dried prior to use. When dry it is quite hygroscopic and, if not used immediately, should be stored in a tightly covered container or in a heated storage oven to prevent absorption of moisture from the air. The finished composition should be treated in the same manner. Color of the wood flour is not always important, but must be considered if light shades are desired. Shavings have been suggested<sup>30</sup> as a substitute for wood flour in certain cases.

**Asbestos.** Among the many grades of asbestos,<sup>31</sup> powder-like material, known as "floats" or micro-asbestos, is used extensively in compositions that are required to withstand, without carbonization, higher temperatures than could be resisted by wood flour or other organic fillers. Articles of good appearance can be molded from compositions containing a short-fiber asbestos, but these are mechanically weaker than those produced with the longer grades.

Care must be used in the mixing of preparations containing long-fiber asbestos to avoid undue breakage of the filler. This is best accomplished when the fibers are treated with the binder by the wet process subsequently described or are well mixed with a finely powdered resin, to which has previously been added the other ingredients. The blending should be done with a minimum of grinding action so that each individual fiber becomes coated with the binder. Since asbestos is a dense solid material, only a very slight amount of impregnation occurs in contrast with wood flour. A sufficient quantity of resinous binder should be employed to insure uniform coverage of each individual filament, as uncoated fibers will stick to the mold and cause blemishes in the surface of the piece. The longer-fiber compositions do not flow readily, requiring extreme care to secure a properly filled mold, and, in general, yield a product somewhat low in tensile strength but with good shock resistance. The surface is inferior to that obtained with wood flour and short-fiber asbestos.

Molded products containing asbestos usually have lower dielectric strength than those with organic fillers, since mineral fillers often include small amounts of metallic iron. A large proportion of the conducting component is in the dust and can be removed by screening through a 20-mesh sieve and discarding the fine material.<sup>32</sup>

<sup>29</sup> R. Meldau, *Z. Ver. deut. Ing.*, 1929, 73, 1315; *Chem. Abs.*, 1930, 24, 2246.

<sup>30</sup> Methods of test are described in Chapter 69.

<sup>31</sup> Swiss P. 128,831, 1927, to Emil Haefely & Cie A.-G.; *Chem. Abs.*, 1929, 23, 2772.

<sup>32</sup> H. Rosenberg, *Kunststoffe*, 1927, 17, 55; *Chem. Abs.*, 1927, 21, 1692.

<sup>33</sup> L. E. Barringer, *Gen. Elec. Rev.*, 1927, 30, 387.

Asbestos in the form of fabric treated with resinous binder is used to make laminated products capable of resisting high temperatures.

**Cotton Flock and Cotton Linters.** Cotton may be obtained in fibers of varying length and is usually employed in minor proportions as a filler for molding compositions of low heat resistance. It is commonly used in conjunction with powdered mica or gypsum, as it greatly increases the impact strength. Cotton flock has a tendency to cluster into small lumps when baled for shipment and should therefore be passed through a screen to break up these masses. Care is required in handling to prevent clotting and insure even distribution in the blended composition.

As cotton is also hygroscopic, the flock should be dried and stored in the same manner as wood flour, particularly if the composition is to be used for electrical insulation.

**Silk Flock.** Silk flock, like cotton flock, is used to increase the shock resistance. It replaces the latter principally in articles that are molded oversize and shaped by machining, since the inclusion of cotton results in a surface that polishes poorly. Silk flock has been found to be superior in this respect.

**Paper and Fabric.** In the manufacture of laminated products, paper and fabric are the important fillers, but paper is also used to some extent in other molding compositions, usually in the form of pulp or ground to a fibrous mass to replace wood flour. Fabric, impregnated with a binder, may be employed in molded articles to give high shock resistance, as in the case of golf club heads. The composition is difficult to mold into complicated shapes because of the poor flowing characteristics, but this may be offset in a measure by impregnating paper or fabric with a synthetic resin, then beating, and mixing with additional powdered binder.<sup>55</sup>

**Mica.** This material is very much in demand for electrical insulation because of its very excellent properties, especially its high insulating and dielectric values and its low losses, even at high frequencies. Resinous binders have been used to build up small flakes or sheets into larger forms, and Frederick<sup>56</sup> has made plates of mica while McCarthy<sup>55</sup> has prepared sheets by showering mica flakes on a machine bed, supplying a liquid binder and compacting the whole by rolling.

Mica alone or in conjunction with other inorganic fillers, such as gypsum, may be used with shellac or phenol-sulphur chloride resins to make molding compositions which may often contain 70 to 90 per cent by weight of these fillers and yield molded pieces of correspondingly high density. The use of 70 per cent of mineral filler with a shellac binder forms a mechanically strong composition, but the phenolic resin binders do not wet or cover particles of mica fully and consequently the strength expected from molding a preparation of this type is not realized. Mica must be finely ground if it is to be incorporated with a phenolic resin and a fibrous filler should be added to increase the mechanical strength. The alkyd resins are well adapted for use as binders for mica.<sup>56</sup> Lloyd<sup>57</sup> has suggested a phenol-urea-aldehyde resin to bond mica, as he finds that wetting occurs more easily. Furthermore, the product is claimed to give less trouble from "tracking" or breaking down and becoming conductive under the influence of an electric arc. Crossley<sup>58</sup> has combined mica with lead borate to form a synthetic

molding composition. A review of processes and materials employing mica has been given by Rossman.<sup>30</sup>

**Powdered Fillers.** Fine inorganic materials such as china clay, gypsum, rotten stone, barium sulphate, slate powder,<sup>40</sup> kieselguhr, siliceous and flint, are used to some extent in molding compositions, but they generally require a reinforcing fibrous or lamellar filler. Large quantities of powdered fillers can be used in certain cases, particularly when price is a factor. The proportion of mineral fillers is especially high in phonograph records, since great strength is not essential and hardness is required. Thermoreactive preparations are usually specified for products requiring greater strength and, therefore, should be incorporated with only a small quantity of mineral powders.

For uniform results the properties of fillers must not change appreciably from one shipment to another. Tests which serve to indicate these variations are also useful guides in the initial choice of a suitable material to meet specific requirements.<sup>41</sup>

Whyte and Lord<sup>42</sup> have incorporated up to 30 per cent of diatomaceous earth, of particle size less than 0.01 mm.<sup>43</sup> into synthetic resin or cellulose ester or ether films. They have reported increased resistance to abrasion and cutting without serious reduction in the transparency.

**Miscellaneous Fillers.** Carbon obtained by the thermal decomposition of graphitic oxides is sometimes of service in the manufacture of plastic materials,<sup>44</sup> as finely pulverized electrical conductors are used in molding compositions to lower the resistivity.<sup>45</sup> Ground ebonite has been suggested as a filler in molding preparations,<sup>46</sup> and Holt<sup>47</sup> has made articles from granulated cork mixed with a binder, while Messer<sup>48</sup> has used resin-coated cork to form articles reinforced with a metal core.

Rubber which has been vulcanized and ground may be employed as a filler, alone or with wood flour, according to Crosley.<sup>49</sup> Pierson<sup>50</sup> has made use of leather scrap in the preparation of a thermoplastic molding composition. Walton<sup>51</sup> has introduced relatively large pieces of furnace slag that have previously been colored by a vitreous coating. The resin is clear, and the filler serves mainly for decoration.

Abrasives have been incorporated in synthetic resin binders, but, in this case, voids should be left between the particles to give the clearances required for cutting. Cellulose acetate<sup>52</sup> and phenol-formaldehyde condensation products<sup>53</sup> have been suggested for this type of work. The abrasive may be coated with a

liquid resinous composition so as to form a non-tacky layer.<sup>54</sup> On the other hand, Brock<sup>55</sup> and Martin<sup>56</sup> have used mixtures which are more or less sticky and gummy, and Novotny<sup>57</sup> coated granules with an adhesive resin which is rendered non-tacky by freezing so that the loose mass may be levelled in the mold to form a uniform, well-balanced grinding wheel.

### COLORING AGENTS

Both dyes and pigments are employed for coloring molding compositions, dyes being preferred in products intended for electrical insulation. When the molded article is to be used with a material which may attack certain dyes, care must be exercised in the selection of the coloring agent. If high heat resistance is required, aniline dyes are sometimes employed, but pigments are more satisfactory over a long period of time. Bone black or carbon black, alone or mixed with a black aniline dye, is sometimes used, while iron oxide and the sienna and umber pigments may be blended in various proportions to obtain the red and brown shades. Manganese dioxide or pyrolusite gives a dark brown or black color.

The dye or pigment must always be very finely ground and thoroughly intermingled with the other ingredients of the composition to obtain an even, uniform shade and full color value. It should also be free from metallic content, to avoid any reduction in the dielectric strength of the molded product.<sup>57a</sup>

### LUBRICANTS AND PLASTICIZERS

The tendency of molding compositions to stick to the mold may be best overcome by the inclusion of a lubricant. Manufacturers of molding compositions guard against sticking by lubricating their materials properly for standard molding conditions, and little trouble should be encountered unless the shapes are very intricate. Stearic acid, stearates and metallic soaps are extensively used for such purposes.<sup>58</sup> The various resins used as binders in hot molding differ so in properties that no general rule can be made and the proper kind and amount of lubricant to be used with any particular composition can only be determined by actual test.<sup>59</sup>

Plasticity and the influence of plasticizers have been given considerable study by various investigators.<sup>60</sup> The primary purpose of including a plasticizer in a molding composition is to increase the flow of the material, thus insuring complete filling of the mold cavity and perfect reproduction, particularly with pieces of complex form. Insufficient flow may result from using too little binder, or it may be caused by too quick reaction of a thermosetting binder under the heat of the mold with consequent hardening of the composition before the press is closed. The difficulty can be overcome by cooling before charging but this increases molding time. Such a resin may have been taken to an unduly advanced stage of reaction before molding, a situation which would accelerate its hardening and prevent it from flowing freely. These conditions can all be improved by

the addition of a plasticizer. This should be a solvent for the resin and in reactive compositions it should either undergo reaction and become infusible or remain in solid solution in the molded material. An excess of plasticizer or a substance incompatible with the composition will result in a spotted surface. Plasticizers may be added to the resin, to the filler or to the molding composition. To avoid surface blemishes or sticking and staining of the mold, it is essential that the mixing be thorough, an operation which may present difficulties.

FIG. 169.—22" x 60" Heavy Duty Plastics Mill with Individual Drive.

In sheeted compositions, plasticizers are incorporated to lower the temperature at which the preparation may be worked, a consideration which is of importance if the material is to be packed in the mold prior to pressing.<sup>61</sup>

#### METHODS OF MIXING

The most widely used procedure for mixing the thermoplastic, and particularly the thermosetting, molding compositions is the "dry method" which eliminates the need for solvents and their subsequent removal and recovery. The process is largely restricted to preparations that are solid and sufficiently hard at normal temperatures to permit grinding without caking or sintering. Liquids may be added but they must be of such character and quantity that they will be distributed uniformly throughout the mix without wetting it to a plastic condition. When large amounts of liquids or soft plastic binders of low melting point are used, the wet process gives a more uniform product.

The dry method consists essentially of pulverizing the resinous binder and

<sup>61</sup> The various plasticizing agents and fluxes employed in molding compositions are discussed more fully in the chapters of this book devoted to the different types of resins. See particularly Chapter 22 dealing with phenol-aldehyde types and Chapter 28 for urea-formaldehyde resins.

grinding this with the other ingredients, lubricant, flux, hardening agent and dyes. The work may be done in a hammer mill or in a ball mill. The fibrous fillers such as wood flour, cotton flock or asbestos are then added and the blending continued until a uniform mixture is obtained. This must be done with a minimum of grinding action to preserve the length of the fibers, and it is sometimes advisable to mix a lubricant with the fillers as a separate operation before adding to the binder.

FIG. 170.—Size 1 Banbury Plastics Mixer for Laboratory and Small Production.

The light, fluffy powder, prepared in this manner, may be given additional treatment by passing between heated steel cylinders revolving towards each other at slightly different speeds. These are so arranged that the distance between the rolls may be varied during operation at the will of the operator to process the material properly and obtain a sheet of the desired thickness. The advantages derived by further manipulation on heated rolls of this type are three-fold. A more intimate mixture of the ingredients is secured by fluxing the resinous binder and coating all of the particles. Second, there is closer adherence of the particles and a decided reduction in bulk or increase in the apparent density. The volume of the composition is an important factor, as sufficiently large mold cavities must be provided to contain the full charge necessary to form the article. With a very bulky material this may be too great for efficient molding and will tend to lower production. Minimizing the bulk also makes shipping more convenient.

of steam or other heating mediums. See Figs. 170 and 171. Use of masticators<sup>43</sup> obviates the need for fine grinding and blending of the ingredients in a ball mill as mastication is performed while the material is hot and plastic. Proper temperature control with thermosetting resins is essential and the hot mixture when removed from the masticator is usually cooled for a short period and then sheeted on differential rolls to chill it rapidly. Quick cooling is necessary as the mass will retain heat over a considerable period of time and may, in the case of thermosetting binders, be converted to the infusible stage.

**Uniformity of Mixture.** The methods thus far described generally require an elevated temperature to effect mixing. When the thermosetting compositions are prepared in this manner, care must be exercised to prevent the reaction from proceeding to an extent that would reduce the plasticity of the mixture and make it difficult to mold properly. Skilled operators are therefore needed and every facility must be afforded for the proper regulation of the mixing process to insure uniform molding characteristics. Control of the progress of the reaction is a somewhat difficult matter at best, and blending of various batches of soft and hard material may be necessary to keep the product within the desired limits of plasticity.

**The Varnish Method.** The varnish method of mixing is of value when heat is to be avoided, since mobility of the ingredients is attained by dissolving the binder in a volatile vehicle, yielding a solution to which the filler and other insoluble components may be added. The material is usually worked in a masticator, which may, however, be of much lighter construction than that previously described because of the lowered viscosity. Mixing is effected by blades which rotate at different speeds and may be periodically reversed. These machines may be equipped with a steam jacket but heat is seldom used. A solution containing approximately 50 per cent of resin and having a relatively low viscosity is thoroughly absorbed by a wood flour filler at normal temperature and the danger of the reaction proceeding too far prior to molding is greatly decreased by this method.

The blended composition is then freed from solvent by drying. Non-reactive, fusible compositions may be satisfactorily treated in ordinary atmospheric dryers but the reactive thermosetting preparations, because of their sensitivity to heat, often require the lower temperatures of vacuum drying. Either shelf or rotary drum dryers can be employed.<sup>44</sup> Following the extraction of solvents, the product is ordinarily ground to a powder and is then ready for use. When sheet stock is desired the granulated material may be placed on rolls of the type already described for mixing, heated to a temperature sufficient to render it plastic and immediately passed through sheeting rolls.

### LAMINATED PRODUCTS

The raw material for making laminated products consists of sheets of paper or fabric impregnated with a resin solution and subsequently dried. By combining a number of such sheets and subjecting them to heat under heavy pressure to bind them firmly together, sheets, tubes,<sup>45</sup> rods and other simple shapes of any desired thickness may be made. These laminated products have exceptionally high tensile and impact strength combined with the other properties found in molded

<sup>43</sup> One type of masticator, known as the Banbury mixer (*cf.* Figs. 167, 171 and 172), provides facilities for the quick handling of raw ingredients, close temperature control and rapid production of mixed material.

<sup>44</sup> The manufacture of phenol-aldehyde resin molding compositions is described in Chapter 22.

<sup>45</sup> W. C. Anderson, U. S. P. 1,595,811, Aug. 10, 1926, to Continental Fiber Co.; *Chem. Abs.*, 1926, 20, 3250.

articles<sup>66</sup> but cannot be molded into intricate designs without special preparation and shaping since the material itself has very little flow.<sup>67</sup>

**Preparation of Laminated Products.** Continuous sheets of paper, fiber or fabric are impregnated with a solution of resinous binder (usually containing 50 per cent total solids) and subsequently dried. See Fig. 172. The operation can be carried out in a manner similar to that used for coating paper, by passing the sheet between rolls, one of which is coated with the resin solution. The material, thus coated on one side, is passed over heated rolls to evaporate the solvent.<sup>68</sup> An alternate treatment is to cover one surface of the fabric or paper with a binder of dough-like consistency, using scrapers similar to those on a rubber spreading machine. If both sides of the sheet are to be coated, dipping in a solution of the binder is the simplest and most effective procedure. The excess may be removed by scrapers and the sheet is then led through a drying chamber maintained at a properly regulated temperature. The heat incident to the last

step effects a partial reaction of the resin which must not be allowed to go too far lest the finished pressed product be weakly bound together.

Sheets containing a resinous binder may be formed in a paper beater by dispersing pulp or other available fiber in liquid resins, or finely pulverized resins suspended in water, the product being later formed into a sheet on screens or in a paper making machine.<sup>69</sup> If the resin is thermosetting, a hardening agent can be added, but in this event the sheet is best dried in a vacuum or on calendering rolls heated to a low temperature,<sup>70</sup> so as to minimize further hardening of the binder. The progress of the reaction can be retarded by drying at a temperature below 40°C. while passing through a zone of reduced pressure,<sup>71</sup> or by treat-

ment with a current of warm dehydrating gas at a temperature below that at which excessive softening of the reactive resinous binder occurs.<sup>73</sup> The use of wood flour has been advocated to aid in the more uniform incorporation of pulverized resinous binders and fluxing agents in paper pulp<sup>74</sup> which is to be sheeted in a paper making machine. Powdered mica in the form of a thick paste, when added to the paper stock before mixing, is stated to give high electrical resistance.<sup>74</sup>

FIG. 173.  
Multiple-Platen Press for Curing Finished Sheets.

*Courtesy R. D. Wood Co.*

In the manufacture of laminated pressboard, it is important to adjust the proportion of resinous binder carefully, although standard material usually contains approximately 50 per cent by weight of reactive resin. Water resistance must be high, the usual specification for phenolic resins requiring that the absorption after total immersion for 24 hours must not exceed 0.2 per cent. If the resin content falls below 47 per cent, the water absorption may exceed this value, but if greater than 55 per cent the sheets are likely to slip over one another in the press.

Slow curing is desirable and frequently is conducted at a low enough tempera-

<sup>73</sup> L. H. Baekeland, U. S. P., 1,842,647, Jan. 26, 1932, to Bakelite Corp.; *Chem. Abs.*, 1932, 26, 1812. British P. 314,937, 1928; *Brit. Chem. Abs. B*, 1930, 111. French P. 663,551, 1928; *Chem. Abs.*, 1930, 24, 699.

<sup>74</sup> A. L. Clapp, U. S. P. 1,684,755, Sept. 18, 1928; *Chem. Abs.*, 1928, 22, 4757.

<sup>74</sup> G. J. Crossman, U. S. P. 1,868,560, July 16, 1932, to Panelyte Corp.; *Chem. Abs.*, 1932, 26, 5441. The impregnated sheets formed by these methods are cut into convenient lengths and hot pressed as described in Chapter 63, or marketed as unpressed sheets to be formed as desired by the purchaser.

ture to allow the treatment to continue for half an hour. Subsequent baking may be resorted to for additional hardness and water resistance.

In addition to the method of impregnating sheets of fabric by coating or dipping the previously woven material, other procedures have been suggested by which the individual threads or cords are treated and subsequently dried. The product may be then formed by placing a mass of the threads into a mold in a haphazard manner to form irregular or interlocking structures<sup>74</sup> or they may be woven into a fabric.<sup>75</sup> Laminated sheets and articles containing a reactive resinous binder may be so formed that the interior portion will not harden to the same degree as the surface. This effect is secured by impregnating the outer layers with a binder containing a greater proportion of the hardening ingredient.<sup>76</sup>

Wood veneer has been utilized as a basis for laminated products, but the thin sheets intended for this purpose may have to be prepared with an alkaline solution before processing in order to prevent sticking to the platen of the press.<sup>77</sup> When coated with a solution of phenol-formaldehyde resin the veneer is liable to warp, and therefore Loetscher<sup>78</sup> has advised placing a partially dried sheet of resin-impregnated paper between the uncoated surfaces of wood which are to be united. Heat and pressure are then applied to form a composite layer. Saturation of the wood under vacuum has been recommended for improving the product, particularly for electrical purposes.<sup>79</sup> Panels containing a middle layer of flexible fibrous material impregnated with a reactive resin to which the outer surfaces may be cemented by hot pressing,<sup>80</sup> and wood veneer combined with a backing or transparent facing sheet of paper treated with a resin,<sup>81</sup> have also been suggested.

Sheets of glass may be united by a plastic to form a shatterproof material, the usual form consisting of two layers of glass with an interposed film of celluloid or cellulose acetate, the whole bonded together to form a composite plate. Many types of synthetic resins have been suggested for use in laminated glass not only as a cementing agent but also as the inner layer.<sup>82</sup>

<sup>82</sup> This use of synthetic resins is treated in the various sections which describe specific preparations. Particular reference should be made to Chapters 22, 30, 34 and 52.

## Chapter 66

### Cold Molding

The process generally known as cold molding was introduced into the United States in 1909. The name was given to distinguish it from the molding of permanently thermoplastic compositions such as shellac, which of course require both heating and cooling. The phenolic heat-hardening plastics were not developed until slightly later.<sup>1</sup>

In general, cold-molding compositions, in the form of loose, slightly sticky powders, are subjected to high pressures in a very short cycle so that the press costs are low. The binders generally employed are cheap asphalts or pitches, which are hardened in the rather slow but inexpensive subsequent baking operation, mainly by evaporation of the solvent. Cold-molded objects can thus be made cheaply even though a two-stage process is used.

The cold-molding industry developed very rapidly and at one time nearly dominated the field of heat-resistant molded products in the United States. Cheaper heat-reactive compositions and the extensive use of multiple-cavity molds and automatic presses, however, have brought the hot-molding type of material into increasing favor because of the greater resistance to shock, lighter weight and better surface finish that are obtainable.<sup>2</sup>

The cheapness of cold-molding is its principal advantage and consequently the binders must be available at low cost. Although some synthetic resins have been employed, these have generally proved too expensive to compete with cheaper materials and mixtures. Even shellac, which has been included at times to a considerable extent in articles of this kind, is displaced by less expensive resins, pitches and asphalts. Thus, because cold molding does not appear to offer a wide field of usefulness for synthetic resins, it is discussed in less detail than hot-molding operations (see Chap. 65). Its interest is mainly as a competitive technique rather than one extensively applied to synthetic resins.

**Uses of Cold-Molded Articles.** One of the principal uses for cold-molded products is in the field of electrical insulation.<sup>3</sup> Other applications also take advantage of the high resistance to heat resulting from the baking treatment to which the molded pieces are subjected, a property entirely lacking in articles made with permanently fusible resinous binders. Cold-molded articles may possess even greater heat-resistance than most hot-molded products.

The exactness of dimension, mechanical perfection and lustrous surface finish obtained by hot molding can in no wise be secured in cold-molded articles. (See Fig. 174.) However, since, inserts may be incorporated with the latter (as with hot-molded articles) they may be used in enclosed equipment where appearance

<sup>1</sup> A. J. Weith and A. V. H. Morv, "Twenty-Five Years of Chemical Engineering"; D. Van Nostrand & Co., New York, 1933, 215.

<sup>2</sup> For a comprehensive comparison of the various methods of molding see Chapter 68. E. Hemming has given a great deal of information especially on cold-molding compositions in his book, "Plastics and Molded Electrical Insulation," Chemical Catalog Co., New York, 1923.

<sup>3</sup> H. Chase, *Electrical Mfg.*, 1933, 11 (2), 13; *Chem. Abs.*, 1933, 27, 2536.

is of no consequence and dimensional requirements are not exacting, particularly when resistance to heat and low cost are considerations of importance.<sup>4</sup>

**Binders and Their Solvents.** The usual binder employed in cold-molding operations is a pitch or an asphalt. Coal-tar pitch admixed with gilsonite is a useful binding composition. The better grades of cold-molding compositions frequently contain varying proportions of drying oils. The addition of stearin pitch is also considered beneficial. The mixture is dissolved in a composite solvent which is made up of a light volatile solvent such as benzol or V. M. & P. naphtha, and a heavy solvent of which anthracene oil is representative. The light volatile solvent serves to dissolve the pitch and gilsonite forming a solution having good penetrating powers, thereby easily mixing with the filler. The purpose of the heavy solvent is to maintain the material plastic on exposure so that it will not dry out completely when kept adjacent to the presses during molding. Enough

Fig. 174.—Cold-Molded Article.

solvent is present to render the composition plastic or slightly moist, permitting rapid molding. The material is partly dried to remove some solvent preparatory to pressing.

**Special Compositions.** The foregoing description indicates the general composition of cold-molding mixtures but modifications are numerous. Even vegetable albumin and casein may be mixed with various fillers to form compositions which can be cold-pressed.<sup>5</sup> Cold-molded articles are sometimes made from asphaltum (softened by the addition of benzol or gasoline) and hydraulic cement, or plaster of Paris, with water added. Objects molded from this composition, with an asbestos filler, are allowed to set and are finally baked or immersed in hot oil to eliminate moisture and fill the pores so as to increase resistance to water.<sup>6</sup>

The following serve as further illustrations of various compositions which are

<sup>4</sup> W. B. Stoddard, *Plastic Products*, 1932, 8, 191.

<sup>5</sup> F. G. Wiechman, U. S. P. 853,995, April 7, 1908; *Chem. Abs.*, 1908, 2, 2457.

<sup>6</sup> C. Batcheller (U. S. P. 1,995,412, Mar. 20, 1935) has prepared a cold-molding composition consisting of asbestos, calcined magnesite, powdered clay (Bentonite) and water.

a departure from the typical ones previously described. Cushing<sup>7</sup> made a mixture of asbestos or other filler with tung oil varnish, stearin pitch and coal-tar pitch being added to prevent the binder from oxidizing too rapidly. A granular mass is obtained which can be cold-molded and then baked for 24 hours at a gradually increasing temperature up to 205°C. A binder composed of tung oil, tar acids and sulphonates from tar acids treated with formaldehyde or hexamethylenetetramine has been suggested by Carter.<sup>8</sup> Steinberg<sup>9</sup> recommended a mix of asbestos, sulphur, coal-tar pitch, stearin pitch and castor oil containing benzol as the solvent, which could be molded without heat at 3-5 tons per square inch pressure and baked at a temperature increasing gradually to 232-250°C. over a period of 24 hours. This, it is stated, yields a tough, durable, insulating product which will resist temperatures approaching those employed in baking, without softening or deformation. Barringer has employed sulphurized oils as described in Chapter 60.

A composition applicable for cold-molded electrical fittings<sup>10</sup> comprises asbestos (40 parts), slate flour (40 parts), asphalt (8 parts), oxidized oil and a drier (8 parts), copal resin or similar material (2 parts). Chosa<sup>11</sup> advocated a process in which heat was employed to mix the ingredients. For example, 40 parts of stearin pitch and 60 parts of asphalt are heated to 245°C., 10 parts of castor oil are added and the temperature raised to 260°C. The mixture is then cooled to 93°C and thinned with 25 parts of benzol. When cold, 286 parts of this binder are incorporated with 1100 parts of asbestos, 66 parts of sulphur (as a "vulcanizing" agent) and 22 parts of iron oxide to form a composition which, particularly after storage, can be molded cold and cured by heating for a period varying from a few hours to more than 24 hours at a temperature rising gradually from 93°C. to 260°C.

Herbst<sup>12</sup> suggested the utilization of a binding agent, such as asphalt, with a polymerizing oil and a solvent together with a filler and an impregnating material, as for instance, furfural.

Articles of fairly high impact strength have been obtained with a composition described by Kurath and Richardson.<sup>13</sup> The binder consisted of stearin pitch, coal-tar pitch, gilsonite, fish or castor oil, and a solvent, together with a filler, a mixture of asbestos, sulphur and iron oxide. This material is formed into thin sheets which are shredded into flakes. The latter give laminations in the molded product and thus increase its resistance to shock.

Colored cold-molding compositions have been made by Coleman<sup>14</sup> from linseed oil, copal, and an asphalt by the addition of iron oxide ground with a dispersing agent and asbestos fiber. The fatty acids of drying oils may be employed as the dispersing material.<sup>15</sup> Bleecker<sup>16</sup> molded acid-proof objects from a pitch binder and a graphite or carbon filler which, after drying, were impregnated with a bituminous substance.

Shellac was molded by Daniels and Snell<sup>17</sup> to form an infusible, insoluble mass,

but the method of preparation is more like that used for cold-molded compositions. A filler (wood flour) is mixed with an alcohol solution of shellac to which a hardening agent, such as triphenylguanidine, has been added. The powder is dried at low temperatures and may be pressed at 260-270°F.

An inorganic binder, for example sodium silicate, mixed with cement and asbestos can be employed in the preparation of cold-molded objects. Such articles are utilized mainly for flame-proof insulation of extremely high heat-resistance, e.g., to insulate the heating element of an electric flat-iron from the upper portion and reflect the heat toward the bottom plate. Following the molding operation, articles made from this type of composition are usually baked at a high temperature, steamed in an autoclave, and then baked again.

**Synthetic Resin Binders.** Many synthetic resins have been proposed to replace part or all of the cheaper pitch compositions and some have had actual commercial use in spite of the higher cost.

Hemming<sup>18</sup> has investigated the utilization of phenol-formaldehyde condensation products. The binder was made from phenol and an excess of formaldehyde, with ammonia as a catalyst. This mixture was heated under reflux until its specific gravity reached approximately 1.17. It was then incorporated with asbestos or other filler to yield a granular or lumpy mix. The composition was molded cold under high pressure and, as soon as the article was shaped, it was placed in an oven and baked until hard. Grünwald<sup>19</sup> suggested mixing a plastic phenol resin and a filler, e.g., asbestos or sawdust, with non-solvents, such as a mixture of water and benzene, to obtain a flaky material, which could be molded cold, dried and then heated to cure the binder.

McCoy<sup>20</sup> also employed synthetic resins. One procedure involved dissolving a phenol resin, shellac or copal in a solution of a weak alkali (e.g., borax) mixing this with a filler, and precipitating the binder with tannic acid. A second method was to swell an infusible resin or pitch such as wurtzilite by adding a mixture of alcohol and benzol and then to incorporate a filler and a soluble binder.<sup>21</sup> He also suggested a mixture of phenol resin and cumarone resin.<sup>22</sup> Phenol-acetaldehyde<sup>23</sup> condensation products have been used as cold-molding binders. Such compositions do not set on heating but retain thermoplastic properties.

It has been suggested that friction materials which are to be subjected to molding may be saturated with an oxidizable binder, with apertures through the material to permit the escape of volatile substances.<sup>24</sup>

Cold-molding phenolic compositions have been prepared by Redman, Weith and Brock.<sup>25</sup> They recommend moistening wood flour or asbestos with a solution of hexamethylenetetramine in a phenol (particularly cresol), adding a potentially reactive resin in powdered form and pressing at room temperature. The molded article is later baked to transform the binder into an infusible and insoluble product. Another method is to mix 50 parts by weight of cresol with 13 parts of hexamethylenetetramine, incorporate this with 600 parts of asbestos pulp and 150 parts of long fiber asbestos in a kneading machine at room temperature and finally add 300 parts of fusible resin. The product is molded cold and

1,673,805, aminonaphthalene; 1,673,806, diphenylamine or other secondary aromatic amines; 1,673,807, reaction product of piperidine and carbon bisulphide; and 1,673,808, sodium  $\beta$ -naphtholate; *Chem. Abs.*, 1928, 22, 2850.

then baked for 2-20 hours at a gradually increasing temperature ranging up to 160° or 200°C. Although the ratio of binder to filler may be varied, the best proportion is 30 per cent of binder to obtain a flame-proof material. A modification<sup>26</sup> consists in mixing a fusible resin with hexamethylenetetramine at 66°C., proportioning the two to yield a product containing 1 methylene group for each phenol group. It is desirable to add to the binder about 5 per cent of its weight of a slowly volatile solvent such as creosote oil. The binder is mixed with 3 times its weight of asbestos and the product dried by exposure to warm air and ground to a coarse powder. This composition may be molded cold and baked for a prolonged period, starting at 38°C. and increasing the temperature gradually to approximately 230°C. Solutions which contain no hardening agent for the phenol-formaldehyde condensation product have also been reported as satisfactory binders. Ethylene glycol, hexalin, ethylene dichloride and Cello-solve were mentioned as applicable solvents.<sup>27</sup> Brock<sup>28</sup> used a powdered fusible phenol resin, with sufficient hardening agent and a plasticizer such as furfural, as a binder for carborundum.

Richardson also suggested the use of condensation products of a phenol and hexamethylenetetramine,<sup>29</sup> the proportions being 6 molecular equivalents of phenol to 1 of hexa. Reaction is continued until approximately one-third completed and then checked by the addition of 5 per cent of light coal-tar oil, after which a filler (asbestos) is added to give a composition containing 30 per cent of binder. This mixture is then dried at normal temperature and ground. A similar binder may be prepared with aqueous formaldehyde and an acid condensing agent such as hydrochloric acid.<sup>30</sup> Turkington has described a binder consisting of a potentially reactive phenol resin and furfural, which, when incorporated with a filler, may be molded cold. The articles so produced are heated to transform the reactive resin but not enough to vaporize the furfural, thus avoiding surface alterations or shrinkage.<sup>31</sup>

A binder for cold-molding compositions may be prepared by gradually adding paraldehyde to phenol or cresol and slightly acidulating with concentrated hydrochloric or sulphuric acid. The paraldehyde is converted to acetaldehyde, the conversion absorbing the heat evolved by interaction of the phenol and acetaldehyde. The reaction is first allowed to proceed in the cold, then the ingredients are heated to form a resin and the acid neutralized. The product, dissolved in acetone, is mixed with asbestos to form a molding composition. A hardening agent, such as hexamethylenetetramine, may be added. Wood flour may also be impregnated with such a solution, and a lubricant, for example aluminum palmitate, added when grinding the composition.<sup>32</sup> Commercial ortho-cresol heated with formaldehyde or paraform yields a resinous material, which forms a satisfactory binder when dissolved in acetone and mixed with a drying oil before incorporating with a filler. The resulting mass, dried in air and ground, can be molded in the cold and baked at a gradually rising temperature.<sup>33</sup>

Weber<sup>34</sup> suggested the use of a very reactive binder made from cresol and formaldehyde in the presence of a catalyst such as magnesium oxide. This is mixed

<sup>33</sup> Carleton Ellis, U. S. P. 1,645,693, Oct. 13, 1927; *Chem. Abs.*, 1928, 22, 174.

<sup>34</sup> H. M. Weber, U. S. P. 1,536,253, May 5, 1925, to Ellis-Foster Co.; *Chem. Abs.*, 1925, 19, 1986.

with a filler and dried in a vacuum to minimize further reaction of the binder. The composition is then roughly shaped by cold molding, followed by hot pressing to complete the reaction of the binder and give the article its final shape. A somewhat similar binding agent was recommended by de Jarny,<sup>35</sup> who condensed phenol or cresol with aqueous formaldehyde in which 15 per cent or more of calcium chloride had been dissolved. The resin in the fusible stage is incorporated with a filler and the composition, when dried, can be pressed cold and heat-treated in the customary manner with or without a mold.

Prouty<sup>36</sup> employed phenol-formaldehyde resins as temporary binders for molded insulation composed of talc. The mixture is molded into the desired shape under pressure, which for spark plug cores may be 25,000 pounds per square inch. After heating the blank at 100-200°C. it can be machined to final shape and size and following this operation it is subjected to a temperature of about 1000°C.

Coleman and Groten<sup>37</sup> have prepared a cold-molding composition containing only a liquid drying oil and a varnish as a binder. This was heated to evaporate the solvent and oxidize the oils, after which a heat-convertible phenolic resin was added and the product molded. Cheetham<sup>38</sup> has described the utilization of a neutral aqueous suspension of a phenolic resin.

A binder comprising the reaction product of phenol or cresol and sulphur chloride is recommended by Votapek.<sup>39</sup> The product may be improved by adding a small quantity of stearin pitch, and incorporation of a filler, for example asbestos, is facilitated by the use of acetone or coal-tar oil as solvents. Trickey and Miner<sup>40</sup> suggested furfuryl alcohol, treated with sulphuric acid, as a binder. McCoy<sup>41</sup> has employed indene, cumarone or their isomers for this purpose. Power<sup>42</sup> advocated cumarone resin as a bond for cold-molded abrasive wheels.

Investigations conducted at the author's laboratory have developed several types of cold-molding compositions of unusual character. For example, 20 parts by weight of acetone, 50 parts of formalin and 5 parts of sodium carbonate are mixed and heated under reflux. The resulting product is freed from water, dried, dissolved in alcohol and sodium or potassium hydroxide added (to catalyze the final reaction) together with the desired fillers.<sup>43</sup>

Another composition contains a binder which is the reaction product of glycerol with a natural resin, such as rosin or a copal, and an acid such as phthalic, citric, tartaric, malic, maleic or succinic. Diluents, softening or retarding agents may be incorporated with the binder.<sup>44</sup>

Still another type of binder for cold molding is the resin made by heating benzotrichloride and phenol until an oily condensation product has formed and reacting the oil with formaldehyde.<sup>45</sup>

**Fillers.** Fillers increase the strength, reduce shrinkage and improve resistance to shock or cold, as in the case of hot-molded articles. Asbestos is the customary material but it generally gives a rough surface. Long-fiber asbestos is best for

<sup>45</sup> Carleton Ellis, U. S. P. 1,793,310, Feb. 17, 1931, to Ellis-Foster Co.; *Chem. Abs.*, 1931, 25, 2312.

strength and resistance to shock but a smoother surface is obtained with a short-fiber grade and consequently a compromise is usually reached between strength and appearance by mixing the two. Wood flour may be added to improve the appearance but it reduces the heat resistance. China clay or other powdered inorganic fillers also improve the surface but diminish the impact strength. Talc is often added to minimize the abrasive effect of the composition on the mold and mica may be introduced to increase the dielectric strength.

**Methods of Mixing.** Pitch, asphalt, gilsonite, resin and other ingredients used to form the binder of cold-molding compositions are dissolved, with or without heat, in benzol or V. M. & P. naphtha in a kettle having an agitator to assist in forming the solution. Fillers are usually incorporated in small batches with the solution to obtain a uniform mass. With a short-fiber or powdered filler the amount of binder may be less than 25 per cent, but when long-fiber asbestos is employed it becomes necessary to increase the proportion of binder. When the batch is first removed from the mixer it is too sticky or tacky to mold and is therefore seasoned by exposure to air to evaporate part of the volatile solvent. If a drying oil is used, it is slightly oxidized by the air and this tends to reduce stickiness. After seasoning, the material is screened to proper size and allowed to remain exposed to the air until it has reached the best molding state. During this second stage the batch may be turned and blended several times a day to evaporate the solvent evenly. A rough test for molding consistency is made by squeezing a portion of the composition in the hand. If it remains compact, it is still too tacky, and if it crumbles to a powder it is too dry and must be blended with a fresh batch to moisten it. At the proper consistency it drops apart in a few lumps. When properly seasoned, the molding powder is placed in air-tight containers to prevent further evaporation and is stored in this manner until used.

**Method of Molding.** The shaping or molding of these compositions is conducted entirely by pressure without the aid of heat. The material, in the form of powder or granules, is weighed or measured by volume. The mold being properly secured in the press with the cavity at the bottom and the force at the top, the measured charge is placed in the mold cavity. The operator first closes the press slowly to drive air out of the composition and then gives the piece 2 or 3 sharp blows in rapid succession, by opening the press about 0.25-0.50 inch and quickly closing it. These blows are needed to set the material and give the article a good surface. The pressure exerted on the cross area of the piece ranges from 5 to 15 tons. The press is then immediately opened and the molded piece ejected. Difficulty arises at times from sticking to the mold and is generally caused by insufficient seasoning of the composition prior to molding. To avoid this, water applied directly to the mold may be used as a lubricant. The articles as they come from the press are rigid but soft and mechanically weak. They may, however, have a tough flexible surface film and in any event possess sufficient strength to withstand the handling necessary for the baking operation.

By the cold-molding process, production may range from 300 to 450 pieces per hour from a single-cavity mold, which is considerably greater than that secured in established methods of hot-molding in hand-operated molds.<sup>46</sup> An exact comparison of press output is difficult but it will suffice to call attention to the fact that molding is more rapid by the cold process. Cold-molded articles must be finished by a subsequent baking operation not required in hot pressing, where the process, except for the removal of the overflow fins and buffing, is completed on removal of the article from the mold.

<sup>46</sup> C. W. Rivins, *Plastic Products*, 1929, 5, 72.

**Baking.** Preparatory to baking, cold-molded pieces are arranged on perforated metal trays to permit free circulation of air and are dried for 24-48 hours at normal temperature before being heat-treated. The stoving or baking operation must be carried out very slowly to prevent blistering and deformation of the piece. The oven with its contents is gradually heated to expel the more volatile solvents at a low temperature and then the heavier and less volatile liquids as the temperature is increased. The size of the articles governs the time of heating, which ranges from 12 hours for small products to 96 hours for thick heavy pieces. The temperature is often raised to 250° or 300°C. If desired, the entire operation of molding and drying can be carried out within 24 hours but this increases the number of defective pieces considerably.

The inflammable nature of the solvents usually employed makes the baking operation a serious fire hazard. No open flame can be permitted in or about the oven, which is heated indirectly by hot air, circulated to maintain a uniform temperature. Means for venting are also necessary, particularly during the early stages of the baking period, to provide escape for solvent fumes and gases.

**Finishing.** The finishing treatment required often involves several operations and is an item of considerable expense. A piece may be knurled, machined or drilled before baking but the usual practice is to bake the pieces with even the overflow fins attached to reduce handling of the soft molded blank as much as possible. At times these fins cement themselves to the surface of the article during baking and form rough lumps difficult to remove. Final finishing of circular shapes is done in a lathe using a file as the tool. Flat pieces are finished on a sanding wheel. Two-part pieces are matched by smoothing the contact surfaces on a sanding wheel, and oversize is ground off in this manner.

A feature peculiar to cold molding is that flat molded surfaces in a plane at right angles, or nearly so, to the direction of pressure seldom or never take a good finish. On the other hand, rounded surfaces, in planes parallel to the direction of force, receive a high luster produced by the friction and heat accompanying the flow of the composition. For this reason flat surfaces are avoided and when circumstances require them they are, as a rule, milled, cross-hatched or treated in some similar manner to improve their appearance. Grinding marks can be removed and flat surfaces polished by buffing in the ordinary manner.

Richardson<sup>47</sup> has suggested that cold-molded articles of improved surface-finish result when the molding material is kneaded under pressure and extruded in the form of strips, which are then cut into blanks for molding.

**Molds.** The molds employed in the cold process, although similar to those for hot-molding, are built more strongly to withstand the high pressures and shocks to which they are subjected. Guide or mitre pins of rugged proportion are used to insure exact alignment. The mold surface is polished to about the same degree as that required for hot pressing. Molds are usually of the single-cavity, positive type; that is, the force is applied in such a manner that the full pressure is exerted on the entire charge of material at all times. This form permits the making of both oversize and undersize pieces and the charge must therefore be measured carefully. The molds also differ in that they must be so designed as to permit the composition, possessing little or no plasticity or flow, to be forced into all parts of the cavity. This sometimes necessitates making an article in 2 or more parts, a practice economically permissible (although it might be formed in 1 piece by hot molding) because of the increased output of cold molding.

In order to facilitate production and ease of removal without injury to the piece, either automatic or hand-operated ejectors are employed, the latter being

<sup>47</sup> L. T. Richardson, U. S. P. 1,944,464, Jan. 23, 1934, to Cutler-Hammer Mfg. Co.; *Chem. Abs.*, 1934, 28, 2082.

generally used with molds for small articles. New molds are usually made with small clearances and are then broken in on a press with a hydraulic pull-back, as the spring-actuated type has not sufficient power to open them. The severe abrasive action of cold-molding compositions shortens the life of molds and their

maintenance is an important item of cost. Aside from injury resulting from negligence or accident, molds usually begin to show signs of wear after 10,000 pieces have been made, and an even shorter life is to be expected when the compositions contain an inorganic binder, e.g., sodium silicate. If dimensional requirements and finish are not important, as many as 30,000 to 40,000 pieces can be turned out before repairs are made. Wear is indicated by the appearance of flow

marks which multiply rapidly. The amount of metal lost can, of course, be readily determined by measuring a molded piece.

**Presses and Equipment.** The inverted ram type of hydraulic press is the one most extensively used in cold molding as it provides an immovable platen for the mold cavity and permits quicker and more convenient charging. The important features of a press are accurate alignment, sufficient pressure and suitable valve equipment adapted for high-speed operation. A small ram is essential when a high velocity is used to avoid the consumption of an excessive amount of pressure liquid and on this account a line pressure of 3000-4000 pounds per square inch is necessary. The presses are equipped with a spring or hydraulic pull-back, which permits rapid opening of the mold, an ejector mechanism and safety devices. Such presses are capable of exerting a total pressure of 10-25 tons. On the upward stroke the ejector is pushed up to any desired position and automatically released, permitting the ejector pin in the mold to reseat in position for recharging. An auxiliary hand lever is provided for holding the pin in place while removing certain articles, such as fuse plugs, which are molded with a thread that must be unscrewed. On presses employing more than 25 tons pressure a separate hydraulic ejector may be used. The one below the bottom platen in Fig. 175, is controlled directly by the secondary valve at the left side of the press. A three-way valve, providing for down-stroke, stop, or up-stroke, controls the application of the main pressure and, as it requires but little effort to operate, facilitates rapid molding. The machines may be equipped with a safety device to prevent accidental closing while the mold is being charged. To serve this purpose a secondary locking lever may be arranged on one side in such a manner that it must be depressed with one hand before the main operating valve, placed on the opposite side, can be opened. In this way, both hands are outside of the press before it can be closed.

To obtain maximum production the presses are equipped with quick-acting valves, made entirely of steel, as brass-seated valves wear out more rapidly under the cutting action of the high-pressure fluid. With steel fittings, oil is used in the hydraulic system to eliminate rusting. Pressure is maintained by means of pumps and accumulators, some of which are described in Chapter 67. The high pressures generally employed require that the hydraulic equipment be guarded against damage by shock absorbers placed at various points throughout the system to take up "water hammer."

## Chapter 67

### Molding Equipment

Molding is an economical and rapid method for the production of a large number of identical articles, but careful selection and design of equipment are as essential as is the use of the proper materials. This chapter is concerned with the types of molds, presses and accessories employed in the application of synthetic resins to the manufacture of molded articles.

**Types of Molds.** The mold is the tool which is used to give shape to the molding material while it is in a plastic state. Inasmuch as the initial cost of the mold represents a considerable proportion of the total expense involved, careful design is necessary. The number of pieces to be made, the material which is to be formed and the probable use to which the finished piece will be subjected must all be considered.

The various types of molds in general use differ chiefly in the manner in which they act upon the material to be formed and are classified as "flash" or "open" molds, "positive" or "closed" molds, "injection" molds and "blowing" molds.<sup>1</sup>

In the flash type the top rests upon the body of the mold, whereas in the positive form a tightly fitting plunger is forced into the lower section. In the former case an overflow channel must be cut around the cavities to collect the superfluous material or "flash." An injection mold is of the positive type but is empty when closed. The plastic material is introduced under pressure through a small port, thus requiring a composition which will stand preheating. The fourth type, the "blowing" mold, is used in the rubber, pyroxylin and glass industries for the production of hollow articles. The pressure on the molded article is exerted by a fluid, such as air, gas, steam or water. Hollow toys are commonly made from pyroxylin sheets or tubes in this manner. In general, this type is not used extensively in the fabrication of synthetic resin products.

Molds for the casting of thermoreactive synthetic resins are frequently made of a fusible metal such as lead. Such molds may be charged with resin before they are fully cold, and may be readily melted and reformed after each charge of resin if the mold is damaged in removing the piece.

Dies for extrusion molding are entirely different from the four types described above in that they give shape to the plastic material while it is being forced through them, and thus are suitable only for forming continuous moldings of uniform cross-section. The dies may, however, be solid, hollow or irregular in shape. These molds must be designed to insure free flow so that all material moves continuously and no "dead spots" are present.

Large multiple-cavity molds are used for the quantity production of radio tube bases, telephone mouthpieces and many small articles such as bottle closures. Sachse<sup>2</sup> has devised a mold for making pieces with re-entrant angles<sup>3</sup> by

<sup>1</sup> L. F. Rahm, *Plastics and Molded Products*, 1931, 7, 386.

<sup>2</sup> W. G. Alpeter, *Plastics and Molded Products*, 1932, 8, 199.

<sup>3</sup> W. Sachse, U. S. P. 1,687,797, Oct. 16, 1928, to Central Scientific Co.

forming these parts against a section of the mold which is removed with the piece and separated from it outside of the main cavity.

**Mounting and Heating of Molds.** The earliest forms of molds were heated by inserting them in a press between heated platens, or by resting the parts of the mold on a hot table. Cooling was effected by transfer to a cold surface or by cooling the entire mass. With the introduction of larger multiple-cavity molds the weight became so great that manual operation was impossible, and permanent mounting in the press was adopted. Improvement in the rate and economy of heating and cooling then became possible by heating the mold alone. When heating and cooling are both necessary, the mold is made hollow or cored, and steam and cold water are used alternately.

FIG. 176.—(A) "Flash" or "Open" Mold. (B) "Positive" or "Closed" Mold.

If heat alone is required, electricity or gas may be used. Electrically heated molds and platens have been much used and recommended, especially for small presses or for installations where high-pressure steam is not readily available.<sup>4</sup> This method is reported to be much more uniform than steam when used with thermostatic control, and is more economical when only one or two presses out of a battery are to be operated. Bell<sup>5</sup> has calculated that about five watts are required for each square inch of platen area in normal work with synthetic resins. Gas-fired platens for hot molding have been used for hard rubber telephone parts<sup>6</sup> and for phonograph records. High-pressure gas is almost a necessity, however, and special burners are required.<sup>7</sup>

The rate of heating and conductivity of molds are important, especially when

<sup>4</sup> R. M. Keeney, *Chem. Met. Eng.*, 1925, 32, 855. *British Plastics*, 1933, 4, 405, 443, 445.

<sup>5</sup> L. M. T. Bell, *British Plastics*, 1931, 2, 519.

<sup>6</sup> A. M. Lynn, *Plastics and Molded Products*, 1931, 7, 73.

<sup>7</sup> L. M. T. Bell, *loc. cit.*

both heating and cooling are necessary. The most important consideration is to obtain uniform temperatures on the various faces of the mold so as to prevent uneven curing and avoid warping or blistering of the molded product. Bronze dies are sometimes used when very rapid transfer of heat is desired, but trouble is often encountered from mechanical failure of the metal. Steel discs for phonograph records transmit heat rapidly enough to turn out two complete ten-inch shellac records per minute with both heating and cooling. This is accomplished by very complete coring of the dies.

**Powder, Tablet and Sheet-Stock Molds.** Molding compositions in powdered form are usually pressed in positive or closed molds. When briquettes, sheet-stock or tablets are employed a flash type of mold is very frequently used. The powder mold requires a cavity large enough to contain the required weight of composition and, in using a resin composition incorporated with a filler of wood flour or asbestos, it is customary to calculate the capacity of the cavity to be  $2\frac{1}{2}$  or  $3\frac{1}{2}$  times the final volume of the finished molded article. If a pre-form is employed the cavity may be the size of the finished piece. The advantage of this is readily apparent as it means less steel to heat up to molding temperature, lighter molds and lower cost in construction, in addition to the convenience and accuracy derived from the use of a tablet instead of a bulky powder which must be weighed for each molding.

The sheet-stock mold likewise requires a cavity of the same volume as the completed article, the sheet being packed tightly into the mold. However, sheet-stock requires some means of softening prior to loading in the press which calls for more equipment and labor.

**Inserts.** Inserts are parts of a finished molded article which are of different material from the molding composition but are set in place or positioned by the molding operation. Inserts may be of various metals such as steel, brass, copper, nickel or silver, or can be rubber, a molded resin part, a piece of laminated sheet or ceramic material. They are usually anchored to the mold in order to insure proper location and position after the mold is closed. This may be done by means of a pin in the mold which fits into a hole in the insert.

Care should be taken that the insert does not prevent the mold from closing tightly, otherwise a poorly molded article would result. This is important with metal parts which pass all the way through a piece. The simplest forms are always preferred, of course, especially those that can be made to close tolerances on automatic machines. For irregular pieces die casting has been used.<sup>9</sup> Peterson<sup>9</sup> has suggested wrapping metal inserts with several layers of cotton yarn before imbedding them in the resin. Metal overlays are often employed for decorative effects on laminated products of all kinds, such as table tops, trays, store-front panels, water coolers, and many other products.

**Materials Used for Making Molds.** Hardened steel is the most generally used material for molds. Since the cost of designing, fabricating and maintaining these tools is very high it is worth while in most cases to use hardened steel, and in special cases stainless steel. Although the initial cost may be considerably higher, the longer life of special molds and the lower cost of maintenance may overbalance the difference in cost of manufacture.<sup>10</sup> In cases where a relatively small production is required or where the design of a mold is of doubtful efficiency, soft steel is employed because slight changes may be made more easily. The unhardened steel mold, however, will require more frequent polishing and if used

<sup>9</sup> *British Plastics*, 1932, 4, 283.

<sup>10</sup> C. F. Peterson, *British P.* 359,353, 1930, to British Thomson-Houston Co., Ltd.; *Chem. Abs.*, 1933, 27, 436.

<sup>10</sup> *British Plastics*, 1931, 3, 71.

in constant production will have to be discarded in a comparatively short time. Gray iron castings may be used occasionally for molds when the peculiar or irregular shapes desired make machining difficult, but they are, of course, very brittle, cannot be well polished and have only a short life. In the manufacture of printing plates a "molded mold" made from synthetic resin with a thin metallic foil on the surfaces has been employed with satisfactory results. This type has been recommended also for various powdered materials.<sup>11</sup>

Alloy steels with special properties<sup>12</sup> have been used extensively in mold construction, and Hohl<sup>13</sup> has described some of these new applications. Steel for

Fig. 177.—Illustrating Slightly Tapered Sides and Rounded Corners.

use in dies should, when hardened, have an ultimate strength in compression of 100,000-350,000 pounds per square inch. For extreme accuracy in molds it is essential to use steels which do not shrink or warp during hardening. This property is usually gained only at the expense of lower strength.

**Design of Molds and Molded Products.** There are no fixed rules for the design of molds although certain general principles have been pointed out.<sup>14</sup> Once the general design is decided upon there are a number of points which must not be overlooked if best results and lowest costs are to be realized, although it is often impossible to incorporate all desirable features. The most important considerations are given briefly below.

Sufficient "draft" or clearance must be allowed to permit removal of the piece

<sup>11</sup> L. M. T. Bell, *British P.* 271,192, 1926, to British Thomson-Houston Co., Ltd.; *Chem. Abs.*, 1928, 22, 1696.

<sup>12</sup> A. C. Row, *British Plastics*, 1933, 4, 496.

<sup>13</sup> J. Hohl, *Plastics and Molded Products*, 1931, 7, 675.

<sup>14</sup> L. E. Barringer, *Gen. Elec. Review*, 1927, 30, 387. H. T. Richardson, *British Plastics*, 1930, 1, 430, 493, 544; 2, 32, 80, 120, 166. E. F. Bachner, *Plastic Products*, 1933, 9, 135.

from the mold. Thus, unless parallel sides are absolutely necessary, there should be, for hot-molded products, about 0.015 inch total taper per inch of length, or an angle from the parallel of  $\frac{1}{2}$  degree on each side, in the case of both outside and inside surfaces. Cold-molded goods require more, about 0.060 inch per inch or 2 degrees from the parallel. This is due to the fact that cold-molded products are still weak and fragile when removed from the mold.

All sharp edges or corners on the piece, into which the material has to flow, should be rounded off wherever possible, to allow better filling and less breakage. Similarly, edges or corners on the mold that come into sliding contact with another portion should be bevelled off, or protected, as by the use of dowel pins, to prevent mutual damage. For example, bevelled edges to be formed by a

*Courtesy Modern Plastics*

FIG. 178.—Machining a Mold Cavity.

plunger should be modified, as a blunt edge is much cheaper to maintain than a sharp one.

Loading and unloading of the mold should be as nearly automatic as possible. Frames or fixtures can be used to advantage on multiple-cavity molds. In general, the number of movable parts in the mold should be kept as low as possible, and the necessary operations in opening and closing should be made simple and foolproof. Dowel pins are of service in preventing the incorrect assembly of hand molds. Adequate knock-out devices should be incorporated even in the simplest hand mold.

Molds must be ruggedly built, and if possible, designed so that delicate parts are protected from mechanical injury whether caused by normal operation or by accidents. The weight of the mold, however, should be as low as possible, particularly in hand molds, for ease in manipulation, and in molds which are heated and cooled, because of the extra time, steam and water required to vary the temperature of the excess metal.

Sunken lettering should be used on the mold, giving raised figures on the piece. These can be readily stamped or engraved whereas a raised design requires removal of the adjacent metal which is much more difficult and expensive. Furthermore, raised letters are more easily damaged in handling and tend to increase maintenance costs.

Dimensions of molded pieces should not be closer than plus or minus 0.005 inch unless absolutely necessary, as unusual precautions are required to maintain closer limits. In large moldings a tolerance of 0.002 inch per inch of length can be attained for hot-molded pieces, and about 0.005 inch per inch for cold-molded goods.

Undercuts should be avoided in general, as they require a complicated mold, and make removal of the piece difficult since it is necessary to disassemble the mold completely in order to withdraw the article. Deep undercuts on the inside of a piece are even more difficult to produce, but shallow ones are used in many molded closures<sup>15</sup> for bottles and jars.

Holes and inserts should have their axes parallel to the line of pressing wherever possible. If this cannot be done, they should be limited to as few other directions as possible, in order to simplify the operation of removing the pins forming the holes. Very small holes, requiring slender pins, are difficult to make. Therefore pin lengths should be limited to two diameters if possible.

Thin sections of any kind should be avoided, especially when heavy walls are also present. Thus, long holes closely spaced, or holes nearer the edge than one-eighth inch are objectionable. Large holes with square corners near an outside surface are likely to cause breakage, and great reduction in cross-section in any plane should be guarded against for the same reason.

Round sections, capable of production on a lathe should be used where practical, because of the lower cost of machine work and the greater ease of molding.

Threads should be as bold as possible, coarse, multiple threads being used frequently on jars and closures to give quick sealing action. Rings or plugs for molding threads can often be discharged with the piece and unscrewed by machine outside of the mold.<sup>16</sup> Knurling should be bold, and in straight lines parallel to the direction of removal of the piece, facilitating operation. Knurling at right angles, or diamond knurling, requires a three-piece mold in order to prevent damage during stripping.

Multiple-cavity molds should be made so that one damaged unit can be replaced without impairing the remainder of the mold. This can be done, for example, by the use of a chase, or major mold which holds the independent molding units, as in molding telephone mouthpieces, described by Alpeter.<sup>17</sup>

**Shrinkage Allowance.** Molded articles may be made to very exact dimensions if the shrinkage of the molding composition is taken into account. The ideal preparation should possess just sufficient shrinkage to allow easy removal of the articles, but at the present time, none are perfect from this standpoint. Those of the phenol-formaldehyde type have a contraction of 0.004-0.009 inch per inch of length. This variation must be calculated when a box with a tightly fitting lid is to be designed, and likewise when pieces must exactly fit into a standard sized cavity in a piece of apparatus. The allowance depends on the material used, and in addition, the contraction will be greater when the piece is removed hot than when it is cooled in the mold under pressure. Shrinkage will depend also upon the pressure at which a piece is molded. There is a tendency for

<sup>15</sup> *Plastics and Molded Products*, 1931, 7, 140.

<sup>16</sup> W. G. Alpeter, *Plastics and Molded Products*, 1932, 8, 199.

<sup>17</sup> W. G. Alpeter, *loc. cit.*

molded pieces to shrink away from the mold cavities, and onto the mold plungers. This is particularly troublesome in the molding of large, deep parts, such as radio cabinets, where there is liability of breakage if the material cools unduly before it is removed from the plunger. Advantage has been taken of high shrinkage to unite parts inseparably. In one case knobs on the tops of tobacco jars<sup>18</sup> have been molded, cooled, and inserted into a cavity in the cover of the jar before the latter had cooled after molding.

The accurate design of molded threads has been discussed by Richardson.<sup>19</sup> It is apparent that the thread will shrink both in diameter and in length, so that

Courtesy Western Electric Co.

FIG. 179.—Cross-section of a Single Telephone Mouthpiece Mold. Three distinct parts are shown: the punch which forms the bell mouth and grill holes, the cavity shaping the exterior and the loose insert that forms the threads.

the size and the pitch both change. This effect is noticeable when a molded and a cut thread must mesh exactly for lengths greater than two diameters. Such cases are rather rare, and when they do occur the difficulty can often be met best by the use of metal inserts. Shrinkage may be readily determined by comparing the dimensions of the cold mold and the cold piece. Similar procedures and shapes will give check figures, but marked variation in either is likely to yield different results.<sup>20</sup>

**Fabrication of Molds.** A well-equipped machine shop is, of course, necessary for the manufacture of molds, and in addition, modern practice requires special hobbing tools. It is usual to do all the machining operations required in the mold with an automatic machine, electrically controlled so that the cutter follows the contours of a master mold or template. The master forms employed may be

<sup>18</sup> *British Plastics*, 1931, 2, 396.

<sup>19</sup> H. T. Richardson, *British Plastics*, 1930, 2, 166.

<sup>20</sup> Values for the contraction of several types of molding preparations are given by H. T. Richardson, *loc. cit.*

very simple. Light metal templates or solid masters of wood, cement, lead or other easily formed material including molded synthetic resin compositions are entirely adaptable for the heaviest cuts. An old or broken mold may be used as a master to make new ones, or a finished article may be used as a master to make a hob, from which molds may be made. Gleason<sup>21</sup> has compared the details of the jig-boring and the "button" method of locating holes accurately, suggesting that the latter procedure is quicker, more accurate and cheaper.

Lynn<sup>22</sup> has given a detailed description of mold making for a hand-set telephone handle which has very irregularly curving surfaces. Two hardened steel

*Courtesy Monsanto Chemical Co.*

FIG. 180.—A Typical Mold Assembly.

master hobs were first made, duplicates of the upper and lower part of the hand-set, and were used to check each final mold. Master cavities were made from the hobs and the molds cut from these cavities by automatic machines were finished by hand to match the master hobs.

**Hobbing of Molds.** The hobbing of molds has gained great prominence in mold production.<sup>23</sup> This method, originally known as hubbing and sometimes called die-sinking, is really the forming of the steel mold itself by pressing a hardened steel hob or hub into a soft steel blank under hydraulic pressure. The procedure is similar to that used in the production of metal coins but should be distinguished from the hobbing of gears, where a cutter is employed.

Hobbing is particularly valuable where a number of identical molds or mold-cavities must be made. The process can be used to make molds which cannot be

<sup>21</sup> L. S. Gleason, *Plastics and Molded Products*, 1931, 7, 658.

<sup>22</sup> A. M. Lynn, *Plastics and Molded Products*, 1931, 7, 73.

<sup>23</sup> *British Plastics*, 1930, 1, 404.

machined and polished by any other means. For example, in the manufacture of a certain fountain pen barrel, the mold is over four inches deep, with twelve polished flat surfaces or flutings running lengthwise, while the inside diameter varies from 7/16 inch to about 1/4 inch. The several hobs of increasing length which were used for this were shaped and polished with relative ease, but the mold cavity made by them could not be machined directly.

The hobbing press thus becomes one of the most important tools in a modern mold shop. The hydraulic pressures required are high, 6000 pounds per square inch and even more being usual, and the press capacities range from 200 to 2000 tons total pressure. The platens are of solid steel, not equipped for heating or cooling.

The hobs are made by regular machine shop methods to duplicate the desired article, or that part of it which is to be hobbled. Sometimes two or more different hobs may be used in the making of one mold. The steel used must be very tough, and capable of being hardened and polished. In the United States a good grade of tool steel with 0.80 to 0.90 per cent of carbon is generally preferred,<sup>24</sup> although some molders favor alloy steels. In England, an alloy with 12 or 13 per cent of chromium and 2 per cent of carbon is widely employed.<sup>25</sup> The steel used for the molds must have a very high elastic limit, and must flow under pressure without crumbling or splitting. Low carbon steel or even very soft pure Swedish iron is generally employed where deep cavities are to be hobbled, but well-annealed carbon or nickel-chromium steels can be used for shallow parts.<sup>26</sup> Such stainless steels are sometimes hobbled<sup>27</sup> although they present difficulties.<sup>28</sup>

The hobbing operation is usually carried out by means of a hobbing shell or ring.<sup>29</sup> The hob fits in the top of this, and the steel mold blank fits in the bottom. The blank should have about 70 per cent as much metal removed from the sides, edges, or bottom as will be displaced by the hob. The exact shape of the piece before hobbing depends upon the size and shape of the impression and upon the judgment of the operator, but the surface exposed to the hob should be machined smooth, polished and lubricated with oil before the hob is placed in position. Pressure of 100-200 tons per square inch is applied, forcing the hob into the mold blank. The soft steel flows out below, and the upper surfaces take the exact shape of the hob, including its finish. Pressing is continued until the required depth is reached, or until the force required becomes excessive. The hob and mold are then pressed out of the hobbing shell, when the hob can usually be removed from the mold without difficulty. In hobbing deep impressions it is necessary to anneal the mold a number of times to overcome hardening caused by cold flow. Some work on hobbing molds in hot metal has been reported,<sup>30</sup> but this is not common practice.

**Hardening and Finishing of Molds.** Steel molds may be made by conventional machine shop methods or by hobbing, but for best results they all require hardening. The case- or pack-hardening process may be used for low-carbon steels<sup>31</sup> and quenching in oil or water for tool steels. Trouble is often experienced from the warping or shrinking of steels during treatment, but this can be overcome by employing special non-shrinking oil-hardening steels,<sup>32</sup> usually at the

<sup>24</sup> H. Chase, *British Plastics*, 1932, 3, 522, 562.

<sup>25</sup> *British Plastics*, 1931, 3, 71.

expense of ultimate tensile strength and elongation. Alloy steels,\*\* containing small amounts of aluminum, chromium, molybdenum and carbon, show low shrinking and warping and take a fine polish which is somewhat corrosion-re-

FIG. 181.  
Hobbing Press.

sistant. They are hardened by heating at about 900-1100°F. (480-590°C.) in ammonia gas and are cooled without quenching. The long time required for this operation has apparently limited their use.

\*\* *British Plastics*, 1931, 3, 71.

The final operations on molds of all kinds are finish-grinding and polishing with emery or rouge and oil. The polishing of the hardened steel mold is chiefly a tedious hand operation and a large proportion of the cost of molds is represented by this work. In connection with the design of molded products some designers are now calling for special dull finishes on the molds, or on certain areas of them, in order to give contrast with the brightly polished sections.<sup>24</sup>

**Repairs and Maintenance.** Careful handling of molds by the molder and the use of hardened steel molds greatly reduces the cost of repairs and general maintenance, but all molds must be kept well greased when not in use (to prevent

*Courtesy Pratt and Whitney Co.*

FIG. 182.—Automatic Machine Designed to Produce Molds from a Master Template.

rusting) and free from abrasives which would mar the surface. Actual breakage of molds is not common but damage may result from many causes, such as careless handling or from foreign material in the composition. Multiple-cavity molds are usually constructed so that the block containing a damaged cavity can be removed and a spare mold inserted. Provision is often made on the loading frame so that a damaged section need not be changed, thus allowing the good parts of the mold to be used until repairs can be made conveniently.

**Molding Presses.** The function of the press in the molding of plastic materials is to exert and hold the high pressures which are necessary to flow the materials and compact them into a solid, non-porous mass. The earlier molding presses utilized the principle of the lever, the screw, or the toggle, but as higher pressures were called for, the hydraulic press came into almost universal use. It was found to be the best means of converting the high speed and low pressure power of the prime mover into high pressure and relatively low velocity required in the pressing of plastic materials. Mechanical molding presses are used in certain cases, however, as in the shaping of preforms from loose molding powder.

<sup>24</sup> F. E. Brill, *Plastic Products*, 1933, 9, 54.

The discovery of the basic principle of the hydraulic press is generally credited to Pascal (about 1653). The essential parts of the machine are a cylinder within which is fitted a ram, the former being a part of an open frame. The ram is forced out of the cylinder by means of a fluid pumped into the cylinder. The top of the ram is equipped with a flat surface or device known as a platen and the under side of the head of the press frame opposite the end carrying the ram is furnished in similar fashion. Thus, by the introduction of fluid to the cylinder, the movable platen approaches the fixed platen and a mold placed between them is subjected to heavy pressure. Water is the liquid generally employed and this is forced into the bottom or end of the cylinder exerting pressure between the platens equal to the area of the ram times the unit pressure of the fluid. In hot presses the cylinder may be copper-lined and gaskets are placed so as to be as remote as possible from the source of heat. Cooling or chilling presses are usually equipped with a "U" packing, which is set in an annular groove near the mouth of the cylinder and so arranged that an increase in fluid pressure expands the packing against the surface of the ram and the cylinder walls, and thus becomes tighter as the pressure increases.<sup>35</sup>

**Platens.** In presses to be used with hand molds, the platens may be cored for the circulation of steam and water for heating and cooling. In some cases where cooling is not required, the platens may be heated by gas burners or by electric heating units built in as an integral part. As mentioned above, steam heat is by far the most frequently used, especially where a number of presses are operated together. The high heat of condensation gives very quick heating, and overheating is impossible when pressure is controlled. In presses equipped with direct-heated molds, the platens are usually drilled or slotted to accommodate the fixtures necessary to secure the mold. Frequently a support, or "bolster," is used allowing space for the knock-out mechanism for ejecting the molded pieces.

Mechanically, the press should be designed to keep the platens in exactly parallel planes to prevent possible damage to the molds or to the press itself. Where hand molds are employed, the surfaces of contact on both mold and platen should be as flat and clean as possible to insure good contact, and thus give the quickest possible heating and cooling. Some means must also be provided for opening the press after it has been closed under pressure. The weight of the cylinder and platen is occasionally relied upon or springs may be provided, but generally auxiliary hydraulic "pull-back" cylinders are used. Separate hydraulic cylinders may be provided to operate ejectors or remove the pieces when cured.

**Rod and Rodless Presses.** The rodless press is the simplest form, the head, sides, and cylinder being cast in one piece of steel. The cylinder is lined and bored, and the head faced at one setting, thereby insuring that the faces are perpendicular to the bore. The rigid sides or uprights permanently maintain this condition. Variation in the size of the opening can be obtained by inserting parallel spacer rings between the head of the press and the top platen. The rod press may be distinguished by the adjustable steel uprights which support the head instead of the cast steel sides used in the rodless type.

The inverted-ram press differs from those previously described in that the ram and cylinder are placed at the top, applying the force downward rather than upward. Provision may be made for a hydraulic pull-back above the main cylinder, which pulls the platen upward when the pressure is released. Cold-

<sup>35</sup> For a detailed account of packing materials and methods, see "Hydraulic Engineering," E. F. Houghton & Co. Research Staff, Philadelphia, 1926.

molding presses are frequently of this inverted-ram type so that the operator will have the lower mold always at the same level for quick loading and discharging.

Presses used for forming laminated material are usually of the rod type, provided with multiple steam-heated platens. With such equipment the impregnated fiber may be placed between polished steel plates and cured under high pressure. Various finishes may be obtained by the use of polished, sand-blasted,

*Courtesy Dunning and Boschert Press Co.*

FIG. 183.—Rod Press.

or engraved plates, and the color or design may be changed by using different top and bottom sheets on each pile of paper or fabric. In the design, installation and operation of multiple-platen presses great care is necessary to ensure equal and uniform heat on all platens so that warping will be reduced and equal cure will be obtained in all openings. This requires uniform piping to each platen, and care to prevent clogging or filling with water. Either swinging or sliding joints may be used in the steam and exhaust pipes.

**Tilting-Head Molding Presses.** The tilting-head press is particularly adapted for work where both sections of the molds must be readily accessible, especially when inserts must be placed in both parts. This construction also allows the stroke of the ram to be shortened materially, effecting a considerable saving in the amount of pressure liquid required. A variation of the tilting head press employs a sliding lower platen for still great accessibility. In another type a rotating frame has been added to the lower platen, together with heating and cooling surfaces so that the mold temperature may be varied by changing from a hot to a cold station.

FIG. 184.

Production of Telephone  
Mouthpieces.

*Courtesy Western Electric Co.*

Lynn<sup>26</sup> has given operating details for tilting-head presses, and Alpeter<sup>27</sup> has also described and illustrated the special fixtures used for loading and unloading when molding telephone mouthpieces. The phonograph-record press is usually of this form, as it is necessary to inspect the upper mold, or matrix, and to place labels in position.

**Angle Presses.** Molded articles with threads, bosses or panels on their exteriors necessitate split molds held together by a bulky chase or retaining ring unless a special press is used. A large amount of heat is required to effect the cure in these heavy molds, and quantities of high-pressure water are needed to force the rams through a long travel. In addition, the whole operation is expensive because of the time involved in handling. The angle press has greatly facilitated work of this description. The usual form employs a horizontal ram to close and open the bottom half of the mold, so that a great proportion of the manual work is eliminated. Presses of this kind have been used in the manufacture of telephone receivers.

<sup>26</sup> A. M. Lynn, *Plastics and Molded Products*, 1931, 7, 73; *Mechanical Engineering*, Oct. 1930.

<sup>27</sup> W. G. Alpeter, *Plastics and Molded Products*, 1932, 8, 199.

**Hydraulic Pressure Systems for Presses.** All hydraulic presses require some source of pressure to close the press and hold it in this position during the period of curing. The first equipment used for this purpose was a hand pump, generally attached to the press. This was extremely slow, as a pump capable of giving the high pressure required can deliver only a very small quantity of water. Combination hand pumps have been developed, with the addition of a larger high-speed cylinder, for use when the power required is negligible, as in the idle part of the stroke while bringing the plunger into position. Pressure is main-

FIG. 185.—Angle Press. In this illustration the horizontal ram *B* of the press is closed and the vertical ram *A* is in open position, leaving the mold ready for charge of molding composition prior to pressing. The valves *G* and *H* control the steam and water for heating and cooling the molded parts. Valves *D* and *E* control the vertical ram and *C* and *F* control the movements of the horizontal ram.

tained by closing the valves, but any leakage or shrinkage of the molding material reduces its intensity.

Mechanical power pumps are now employed almost exclusively. The first of these was the reciprocating pump often built with two sets of cylinders and an automatic device to change from low pressure to high pressure when the resistance of the press increased. A by-pass, or relief valve, is necessary to prevent damage to the equipment if an accumulator is not used. Such small reciprocating pumps were sometimes arranged one to each press, giving a convenient, self-contained unit of press and pump. This proved to be inefficient, however, and large hydraulic pumps with accumulators are much more generally used where a number of presses are operated together. The pumps of greater capacity are mostly of the multiple cylinder type, either vertically or horizontally mounted, and usually are fitted with individual motor drives and reduction gears. Steam pumps have also been employed.

An accumulator is a reservoir which is added to a hydraulic system to allow flexible operation. It will maintain pressure for a short time even when the pump is turned off, and is also capable of furnishing large quantities of water for a short period of time. An accumulator of some kind is installed on almost every high-pressure system, and may be used on an auxiliary low-pressure system, although low-pressure lines are often supplied by centrifugal pumps, thus making them flexible and efficient, even without the addition of an accumulator.

**Types of Accumulators.** In the most common type of accumulator the pressure is maintained in the system by a dead weight, usually of metal, supported on a ram which is free to move up and down in a cylinder. The total weight supported per unit area of the ram determines the pressure in the system. When the pump is operating, the ram and weights are raised, falling when water is

FIG. 186.  
Single-Opening Curing  
Press Fitted with Indi-  
vidual Belt-Driven Pump.

*Courtesy R. D. Wood and Co*

withdrawn. This motion of the accumulator may be utilized to operate the pump controls, opening a by-pass valve which allows the pump to run without load when the weights reach the top, and closing the valve again when approaching the bottom of the stroke. The capacity or volume of the accumulator cannot be readily changed. The pressure is constant, whether the weights are at the top or near the bottom, and can only be altered by varying their mass.

The design and capacity of the accumulator and pump depend upon the number of presses operated, the frequency of operation, length of stroke on hydraulic pressure and many other factors. Care should be taken that the accumulator is sufficiently large to avoid rapid drops of the weights, as the inertia of the falling mass will cause severe hydraulic shocks in the system. A larger ram is more expensive and requires heavier weights but a shorter stroke for the same capacity.<sup>28</sup>

The hydropneumatic type of accumulator may be used when the hydraulic pressure must be changed frequently, or when solid foundations are not available for a weight-loaded type, as for example, on the upper floors of buildings. This

<sup>28</sup> W. F. Lent, *Plastics and Molded Products*, 1931, 7, 671.

type reduces hydraulic shocks also, as the weights on the hydraulic ram are replaced by air pressure. The air may be at equal pressure, acting on a ram of the same diameter, or of lower pressure on a correspondingly larger ram. Tanks, or "air bottles," serve to increase the volume of air under pressure, and thus reduce the variation in pressure from one end of the stroke to the other. A tail-rod attached to the floating piston projects from the water end of the cylinder and controls the pump in the same manner as with a weight-loaded accumulator.

In another type of hydropneumatic accumulator the air pressure is lower than the hydraulic pressure, balance being maintained by the use of cylinders and

FIG. 187.—  
Placing Preformed Tablets in the Press.

*Courtesy Bakelite Corp.*

plungers of different sizes. In this case the plunger on the air cylinder is attached to the hydraulic cylinder, forming the moving part between the stationary air cylinder and the stationary hydraulic plunger, and replacing the floating piston in the equal-pressure type. The pressure ratio is the inverse of the ratio of the areas of the two cylinders. The capacity is that of the hydraulic cylinder, and operation is exactly similar to that of a weight-loaded accumulator. The percentage change in pressure is proportional to the volume of the air tank attached to the air cylinder. Installations have been built using steam pressure instead of air pressure. The differential cylinder principle is also commonly used in the pressure "intensifier" in which case a liquid is used on both low and high pressure sides. The volume which can be delivered is small, but tremendous pressures can be attained.

**Mechanical Power Presses.** As stated at the beginning of this chapter, the earliest presses used for molding were mechanical in principle. The hydraulic press is now widely used, but the older types have been adapted to molding work and are largely used in the making of preforms.<sup>60</sup> The mechanical molding press has all the advantages of a self-contained unit, and can be located without reference to accumulators or hydraulic piping. By the use of electric or gas heating

FIG. 188 —

Removing Molded Closures from  
the Press Ready for Finishing.

*Courtesy Bakelite Corp.*

it can also be made independent of steam lines, or high-pressure steam boilers. More presses can be added at any time without danger of overloading existing pressure or steam-heating equipment, which is a consideration in planning accumulator systems.

Several types of presses are available, some using the toggle principle, with pressures up to 200 tons, some a double lever system by which pressures of 800 tons are developed and others a combination of cam and toggle for shallow molding, and a rack and pinion for deep molding where longer strokes are necessary. These presses may be operated manually, semi-automatically or automatically. Mechanical toggle presses, belt-driven from line shafts, are used to some extent in phonograph-record pressings operating at lower pressures than hydraulic presses in the same work.<sup>60</sup>

An unusual type of mechanical press, using the impact power of a falling

<sup>60</sup> See Chapter 68 for preforms and preforming presses.

<sup>60</sup> See Chapter 68 for details of record pressing.

weight to give the required pressure, has been described by Bradley.<sup>41</sup> It is reported that good results have been obtained from a cold-molded type of material by placing the dry powder in the cold mold, compacting slightly to remove air, and then, by dropping a weight with an energy of about 1200 foot-pounds on the plunger, compressing the material into a solid article, firm enough to withstand the handling of subsequent baking treatment.

**Automatic and Semi-Automatic Presses.** Equipment, capable of producing molded articles with little or no attention from the operator, is the result of the demand for greater production and lower costs. The semi-automatic devices with which the operator charges the molds, starts the automatic cycle, and removes the finished pieces are, however, much more common than fully automatic equipment. Controls of this sort can be attached to either hydraulic or mechanical presses. Molds are mounted on the platens, usually on so-called "bolsters" or die carriers, which allow space for the operation of the ejector pins in the removal of the finished piece.

The ejector mechanism may be operated by the opening of the press or by independent means. In old types it was sometimes necessary to close the press after ejection in order to return the knock-outs to the proper position for re-loading. Independent ejectors are usually limited to hydraulic presses, where separate cylinders may readily be installed to actuate them.

**Timing Mechanisms.** The automatic type of press is usually controlled by motor-driven valves. Several presses in a group may be operated from one timing control as is done in phonograph record pressing. The cycling control may be automatic so that the presses open and close continuously. The operator is merely required to place labels and stock in position, and remove the finished record and flash. If he should be late, the press goes through a cycle without any stock and of course produces no record. Another method used is to operate a timing lineshaft continuously, but to let the operator start the cycle for each press, for example, by closing the head of the press or by pushing a connecting lever. This has an advantage in that a slow operator does not miss a complete cycle, but can start when ready. He can control the start but cannot otherwise change the cycle. In both this system and the automatic timing described above, the total cycle time can be varied by changing the speed of the line-shaft drive, but the mechanism at each press must be altered in order to change, for example, the ratio of heating to cooling time.

Signal and recording instruments are available in various combinations,<sup>42</sup> which may be applied to molding presses in any way desired. One installation has a control which is set for the minimum time necessary to insure water-resistance in urea-formaldehyde products. If the operator opens the press too soon a light is turned on and a bell rings to attract the attention of the foreman. Heat indicators are available which show by colored lights the temperature of the press. Recording controllers will indicate the exact time of opening and closing of the press while operating automatically at any time of cure desired.

The use of automatic molding machines is warranted only in cases of large and continuous production with little or no change in the design of the product, as for example radio tube bases. In style goods, such as lipstick cases, cigarette holders and novelties of all kinds, where designs are changed frequently, or production is likely to be intermittent, the initial expense is likely to be greater than the saving.

# Chapter 68

## Methods of Molding

In the actual molding operation as applied to synthetic resins there are so many procedures and minor variations in process, that it is desirable to classify the field to correlate the differences, as far as possible, and to indicate the advantages of the methods.

The first requirement is a mold which gives the material the required shape, finish and size.<sup>1</sup> The composition must then be softened, made to fill the form perfectly, hardened, and finally separated from the mold. Usually certain finishing operations are required, such as trimming or polishing rough edges (see Fig. 189), but these, although adding somewhat to the cost of production, are relatively unimportant.

### TYPES OF MOLDING

The methods of carrying out these various steps in the molding process, the material used and the characteristics of the finished article determine the type of molding. The simplest operation with synthetic resins is the casting of a non-reactive material, and the most complicated is probably the hot molding of a thermoreactive preform which requires cooling after curing. Table 68 (see next page) classifies the various types, some of which have names that are often misleading to one not familiar with that particular branch of the plastic molding industry.<sup>2</sup>

**Casting of Synthetic Resins.** The simplest operation, that of casting a fusible resin, is frequently used where sealing or luting is required, as in mounting radio transformers. Grant and Farren<sup>3</sup> have described a sulphur-cumarone resin-filler mixture for sealing electrical apparatus. Non-reactive cast resins are not extensively used, because, if they have a sharp enough melting point, they generally tend to have the brittleness associated with crystalline materials rather than the toughness of colloids.

At one time the casting of phenol-aldehyde resins (with subsequent reaction at relatively low external pressure) was deemed to be commercially impractical, but now it is used to procure colored products which readily permit machining. The resin is allowed to react under controlled conditions until it is almost converted to the insoluble stage whereupon the hot, gelatinous mass is poured into warm lead molds and allowed to harden by further chemical reaction at controlled temperatures.<sup>4</sup>

A method of casting multi-colored laminated materials has been described by Helfreich.<sup>5</sup> Plates of hardened resin, formed by either casting or cutting, are supported in a mold and more resin which may be of a different color is cast between

<sup>1</sup> See Chapter 67 for description of the equipment used in molding.

<sup>2</sup> A few highly specialized operations have not been included since they do not fit into the table readily. For example, the method best described as "plastering" or modeling, by which large tanks are finished with resinous compositions, has been omitted.

and around them. A permanent bond is said to be obtained without cloudiness or irregularity at the boundaries. A similar result may be achieved<sup>6</sup> by inserting a series of slightly separated nickel plates into the fluid mass of resin, which is hardened by heating, withdrawing the plates and filling the space with material of a different color. Sharply defined effects have been produced<sup>7</sup> by filling containers, such as tubes of cellulose acetate, with a colored liquid resin, immersing these in a mold in which they are surrounded by a similar material of contrasting appearance, and hardening the entire mass.

Weber<sup>8</sup> has made variegated rods of artificial horn or synthetic resins by placing irregular-surfaced layers of composition loosely in a mold and filling the interstices with a liquid or pasty binder. Deutsch and Thorn<sup>9</sup> used a mold, without a bottom, suspended in molten metal to allow easy removal of the finished article.

**Thermoplastic Molding.** The molding or modeling of plastic products softened by heat is a very old industry.<sup>10</sup> Asphalt and the natural resins (shellac, copals and rosin)<sup>11</sup> formed the basis of a well-developed art long before the invention of synthetic resins. Shellac molding technic is applicable to all fusible synthetic resin compositions and a description of it will serve to illustrate the general practice.

The molding of shellac compositions on a small scale requires only a cooling

press and a hot plate heated by steam at 60-100 pounds pressure. The composition, made by thoroughly incorporating shellac (or synthetic resin) with fillers, is prepared in the form of sheets from which pieces are cut of appropriate size to fill each mold. These "blanks" are softened on the steam plate by the molder as he requires them, since such mixtures become brittle and worthless if heated for too long a period. The empty molds are heated in contact with the steam plate to the required temperature, about 80°C., filled with the softened blanks, and placed in the cooling press. The pressure applied, ranging from 700 to 2000 lbs. per sq. in., forces the softened composition to take the shape of the hot mold. After cooling in the press, the piece is removed and the cycle repeated. The finishing consists of removing the fin or flash, formed by the extrusion of material between the parts of the mold, and final polishing. Excessive temperature must be avoided during the entire operation, particularly in molding, inasmuch as it causes sticking, blistering and loss of finish.<sup>12</sup>

Another method of molding thermoplastic preparations is used to make large bulky objects such as storage battery boxes of asphalt or similar fusible materials. This method, in which the mold is not heated, is often called "cold molding,"<sup>13</sup> especially as it is now carried out in rubber factories where the hard rubber battery boxes replace those formerly produced.

Battery boxes are made of an asphaltic composition, usually containing gilsonite,

<sup>12</sup> Further examples of the molding of fusible or thermoplastic materials on a large scale in direct-heated molds are given in the section on Molding of Phonograph Records (p. 1334) which describes the use of shellac mixtures and the thermoplastic compositions containing vinyl resins or cellulose

4, 446.

<sup>13</sup> It has no connection with the cold-molding process of Chapter 66, in which the molded product requires baking to harden it.

a flux (a softer residual asphalt from oil refining or a low-melting cumarone resin), acid-resisting mineral fillers low in iron, some kind of fiber (asbestos, a long cotton flock or short cotton linters) and sometimes a small amount of new or

FIG. 189.—An Abrasive Band Grinder or Sander Employed to Smooth Molded Synthetic Resins.

reclaimed rubber. The asphalts are melted and mixed with fillers and other ingredients in a kneader or masticator until homogeneous. The mass is divided into lots of 6-10 lbs. which are pressed, while hot and plastic, in collapsible water-

FIG. 190.

Molding with Preforms: Loading Tablets in Mold.

*Courtesy Bakelite Corporation*

cooled molds. Heating of the mold is unnecessary since the material flows into place before it has time to chill.

**Cold Molding.** The method widely known as "cold molding" consists of subjecting a special molding powder to very high impact pressure in a cold mold,

removing the piece at once, drying and baking without pressure under carefully controlled and gradually increasing temperatures.<sup>14</sup> The materials used are mostly the cheap asphalts and pitches with some shellac and cheaper natural resins, and sometimes include synthetic resins. High proportions of fillers are used (especially asbestos) and the mixture is fluxed with a small amount of solvent, sometimes a drying oil. In comparison with hot-molded products, those made by cold molding are usually cheaper, weaker and heavier, and have inferior surface finishes.

Certain refractory ceramic materials are molded by a very similar process, but they, of course, are burned at temperatures approximating 1000°C. These are also called "cold-molded" products, although they are sometimes distinguished as "cold-molded refractory" as compared to "cold-molded non-refractory."

#### PREFORMING OF MOLDING COMPOSITIONS

In hot-molding thermoreactive compositions, it has often been found convenient to convert the molding powders into the form of compressed masses variously

*Courtesy Arthur Colton Co.*

FIG. 191.—Single-Punch Preforming Press.

known as tablets, briquettes, pellets, pills, or preforms. (See Fig. 190.) They are made in machines similar to the pill machines which have been used in the pharmaceutical field for many years. Their production is really a molding operation and is properly considered in this separate section.

Tablets or preforms are made from the molding powder by applying high

<sup>14</sup> Details of composition, properties and manufacture are given in Chapter 86 together with descriptions of cold-molding presses.

pressure (five or six tons per sq. in.) quickly and without heat. The operation is very similar to the cold-molding process, except that no solvent is used and the treatment does not compress the material completely, but only causes the particles to cohere. The preform must be strong enough to be handled, and must soften and flow without crushing under the final hot-molding pressure. An average volume reduction is 50 per cent, so that a powder with an original bulk factor of  $2\frac{1}{2}$  would yield a preform of  $1\frac{1}{4}$  to  $1\frac{3}{8}$  which, of course, would be pressed to unit volume when all air is expelled in hot molding.<sup>15</sup>

*Courtesy F. J. Stokes Machine Co*

FIG. 192.—Rotary Preforming Press.

The shape of the preform may be made a close duplicate of the part to be molded, and the same general rules of mold design hold for preforms as for finished articles. One serious difficulty with preforms, however, is the making of deep narrow shapes. Nevertheless rectangular pieces with holes for inserts, pins or positioning rods, have been successfully made. The length and width of the preform should be slightly less than those of the finished article, and plenty of clearance should be allowed for holes. The thickness is then made sufficiently great to furnish the required amount of material for the final molding operation. Preforming molds should be smooth enough to prevent sticking but they need not be highly polished.

For larger pieces a number of preforms may be used, all alike or each made

<sup>15</sup> Methods of determining bulk factor are given in Chapter 69.

to fit in a particular place. One or more balls<sup>16</sup> are sometimes used because they can be charged more quickly than other shapes.

**Preforming Presses.** Preforms are now molded exclusively by mechanical presses, although at one time small hand-operated hydraulic presses, somewhat like those used in cold molding, were employed. These had the advantage of allowing metallic inserts to be molded into the preform. Inserts are now generally omitted, grooves or depressions being left to accommodate them.

Two kinds of preforming presses are now in extensive use. Single-punch models are used most frequently for special shapes, small runs and general work, and rotary machines for quantity production. (See Figs. 191 and 192.) The former has a capacity ranging from 40 strokes per minute, up to 80 or 90 with small pieces. The rotary model, because of the large number of punches and dies used, can turn out 300 to 700 pieces in the same time. Where production does not warrant the expense of a full set of punches and dies, the rotaries can be run with a lesser number by plugging up the unused openings, and the output can still be maintained at a rate several times faster than from a single-punch machine with the advantages of more accurate work, smoother operation and low die-cost.

In either case the loose molding composition is fed from a hopper into a measuring device which determines the weight of the preform by the volume of the loose powder. For successful operation, all machines, therefore, depend entirely upon the uniformity of its density. The pressure must be applied slowly in preforming especially when very fine material is used, so that the air originally entrapped between the grains will escape. Variable speed drives may be required on this account for maximum efficiency.

**Granulating of Fine Powders.** Rotary machines are also used for granulating particularly bulky molding powders to reduce their volume and to make preforming easier. They compress the powder in the regular way after which the tablets are broken up by a granulator and re-pressed.

#### MOLDING OF HEAT-CONVERTIBLE RESINS

In the molding of heat-convertible or reactive resins the fusible composition is placed in the open mold, which is closed and subjected to heat and pressure for a specified length of time, after which the piece is removed as a finished infusible mass of the desired shape. The charge may be used in any of three forms, powder, preformed tablets or sheets.

**Pressures.** The molding pressures required vary considerably but are high in comparison with those employed in the rubber and celluloid industries and lower than those used in cold molding or in preforming. About 1 ton per sq. in. is generally used on phenol-aldehyde compositions and 1-2.5 tons per sq. in. on urea-aldehyde preparations. Often the pressure applied is considerably in excess of that actually required for proper shaping of the material. Intensities which are substantially lower than 1 ton per sq. in. may produce a thick fin or flash which is objectionable, but excessive pressures will damage the mold.

**Temperature and Time Requirements.** The temperature and time required in the molding of thermoreactive materials are directly related, and, of course, depend on the composition. The working range is from 300-450°F. (about 150-230°C.) for phenol-aldehyde products, with most work done between 300-350°F. (150-180°C.). Blount<sup>17</sup> has stated that light-colored compositions, shock-resistant articles containing pieces of woven fabric, or moldings requiring flow of the

<sup>16</sup> H. M. Buckman, *Plastics and Molded Products*, 1931, 7, 679.

<sup>17</sup> C. W. Blount, *Plastics and Molded Products*, 1931, 7, 660.

material into deep or narrow parts may often be advantageously molded at even lower temperatures. The time required for cure or reaction is reduced with greater heat, but the total time of the cycle may be increased, and the yield of perfect pieces lowered since better control is required to prevent waste. For example, above 375°F. (190°C.) it is usually necessary to cool the mold somewhat before removing the pieces and so prevent blistering or pitting of the surface.

The most common method of heating is by saturated steam at 80-175 lbs. per sq. in. pressure (corresponding to about 325-375°F. theoretical temperature at sea level). At 350°F. (176°C., corresponding to 120 lbs. steam pressure) most phenol-aldehyde compositions can be cured and removed from the molds without special cooling. The time required for small pieces is from 1 to 8 minutes. Resorcinol-aldehyde resins in thin sheets, however, can be cured at higher temperatures (around 450°F.) in 5 to 10 seconds.<sup>18</sup>

With the light-colored urea-aldehyde molding powders the temperature may be advantageously maintained in the lower ranges, often as low as 270°F.<sup>19</sup> and usually not over 300°F. Rogers<sup>20</sup> has called attention to the necessity for proper cure in developing water-resistance. Pieces with thick sections should be cured at the lower temperatures to prevent case-hardening and those with inserts must be treated with special thoroughness. Parker<sup>21</sup> has stated that British practice is to cure urea-aldehyde compositions at 280-290°F. (140-145°C.), and phenol-aldehyde at 320-330°F. (165-170°C.). Information on time<sup>22</sup> required for cure is seldom quoted exactly, since it depends on many factors, and must be worked out in each case to insure best results.<sup>23</sup>

**Molding of Powders.** In practically all molding of thermoreactive materials the composition is charged into a hot mold. Inserts may be warm or hot when set in position, or they may be placed in the mold and allowed to heat before the composition is added, as this improves the flow of material around them and gives a better anchorage. Positioning rods, on the other hand, should be inserted as late as possible and should be cold, to prevent adhesion and to allow easy removal. They may be cooled in water before insertion. The required amount of powder is placed in the mold and tamped down.

In handling the composition in powdered form it is necessary, especially when using positive molds, to weigh each charge accurately. Limits must be set at 1/64 of an ounce if the articles are small. Less accurate weighing will serve when flash molds are employed.

**Molding of Sheet Material.** Sheet material is generally used in the preparation of shellac and similar thermoplastic compositions but only to a small extent with the various thermoreactive materials. The stock is placed on a steam-heated plate, which is usually covered with a cloth (or by other means of partially insulating it from the hot surface) and allowed to remain long enough to soften. Then it is cut to a slab of the desired size, placed in the mold by hand and pressed. Powdered or granular thermosetting compositions have always been considered superior to those in sheet form because they cure faster and, at the same time, eliminate the necessity for hot tables. Mottled or striated articles may be made by mixing coarse fragments of sheet stock of different colors before molding, controlling the result by varying the hardness or flowing characteristics of the

<sup>23</sup> Methods for the determination of time of cure are given in Chapter 69.

different colors. Flake material is commonly used in molding by injection and mottled effects similar to wood or marble may be produced.

**Molding with Tablets or Preforms.** The advantages of charging the mold with a tablet of preformed material are so numerous that this method is widely used for the majority of moldings of thermoreactive materials in the United States, and extensively in other countries. Preforms make possible the use of the lighter and longer-lived flash-type molds. Inasmuch as they are already compressed, full molding pressure can be applied at once, "breathing" of the mold is usually not necessary, and their good heat-conductivity allows them to soften and flow quickly. Products made from tablets, which may be preheated to shorten cure, have the additional advantage of thin fins and hence small waste. Often this overflow from the hot-pressing of tablets can be remolded since it does not receive either the heat or the pressure necessary for cure. The spongy mass obtained as overflow may be mixed with fresh material and reworked, although this is not generally done on high-class goods because the low price of new composition does not warrant the risk of reducing the quality due to the presence of partially reacted resin.

Tablets eliminate the labor, inconvenience and waste of material occasioned by the use of sheet stock which must be carefully preheated on a steam plate and painstakingly packed in the mold. They possess the good qualities of the powder for most purposes and, in addition, greatly increase the output of the molding press. It must be borne in mind, however, that the use of tablets involves additional costs for molds and the preparation of the tablets, and that they are impractical when only a relatively small number of articles is required unless a standard pill can be utilized. Some molders hold that they can secure a more uniform finish on their products by using powder instead of preforms, but in general the former is used for small orders, for complicated shapes, for certain pieces with inserts, and, of course, for compositions which cannot be preformed satisfactorily in high-speed machines.

**Molding Fixtures and Accessories.** Various accessories have been developed to aid the operator in loading and unloading the press. Special winders or "spiders" are sometimes used to open hand molds in addition to the arbor press that is usually available. Charging-frames are also employed, particularly for large, multiple-cavity molds. Most presses are single-acting, so that any method which will speed up the ejection of the finished articles and charging of the new material is valuable. Alpeter<sup>24</sup> and Lynn<sup>25</sup> have described a rack for removing forty-nine telephone mouthpieces at one time. All molded products do not lend themselves to such easy handling, but usually many cavities can be charged at once. (See Fig. 193.) Alpeter has also described a rack for placing the metal bushings which form the threads at the bottom of a telephone mouthpiece. This can be applied to most inserts that are not anchored to the mold.

A frame carrying individual hoppers for each cavity can be used to drop the proper amount of powder into all portions of a multiple mold simultaneously. Simultaneous charging of preforms may be effected in the same way. Ball-shaped preforms can be fed by gravity and, as mentioned by Buckman,<sup>26</sup> may be preheated while rolling. The treatment must be such that if, for any reason, production is retarded or halted temporarily, the material will not be overheated and ruined. Preheating may be effected by a conveyor which passes through a small oven, or separate electric ovens with screen-bottom trays may be installed for each press

<sup>24</sup> W. G. Alpeter, *Plastics and Molded Products*, 1932, 8, 199.

<sup>26</sup> H. M. Buckman, *Plastics and Molded Products*, 1931, 7, 679.

or pair of presses, the preforms being left in just long enough to give the required degree of heating.

**Removal of Threaded Parts.** The removal of parts in which threads have been molded has always been a time-consuming operation. The difficulty may be partially solved by ejecting the bushing or plug containing the thread with the piece, loading a new metal part, and unscrewing the bushing or plug while outside of the mold. It has been suggested to remove bottle, jar and tube caps by

*Courtesy Catalin Corp.*

FIG. 193.—Making a Lead Mold.

springing them off over the threads of the mold without unscrewing, a practice which is occasionally possible due to higher elasticity of the material when hot. Shallow, rounded threads rather than sharp, square, or deep threads make this easier. Such methods of removal allow the inclusion of a retaining ring, molded on the inside of the cap to keep the cork liner in place.

#### EXTRUSION MOLDING

Extrusion and injection molding represent two points of view of the same action. If a plastic material is extruded from a receptacle in the form desired by applied pressure, then it can be said to be molded by extrusion. But if the composition is forced from this same container into a cavity which gives it the required shape, it has been molded by injection. Thus, although the two operations start out alike there is a real distinction between them. Forming of plastic materials by

extrusion is very old practice and has been used extensively in handling clay, soap, glass, celluloid, rubber and many other materials, in making pipe, tubing, tire treads, lead cable, brick, and carbon electrodes for arc lights.

This process has been applied to cellulose acetate and to vinyl resins. The extrusion of vinyl resin compositions in bars, tubes and moldings has been described by Davidson and McClure.<sup>27</sup> Leggat<sup>28</sup> has also reported apparatus and methods for forming rods or tubes of casein by this method.

Reactive resins have been extruded successfully, both in Germany and in England, according to Jones,<sup>29</sup> who prefers to call the operation *continuous molding*. The material in powdered or tablet form is fed into a hopper and forced by a ram through a molding zone. This consists first of a cooling portion where the powder is pressed into a compact mass of the desired cross-section, followed by a section where further heat and pressure are applied. It is thoroughly cured here and, after passing through a final stage designed to compress the material, emerges as a finished continuous molding. Many different shapes have been made by this method, including rods, tubes, beadings and special forms. Metal tubes can be coated on either the inside or outside, continuous sheets can be made, or perforated metal sheets covered. Extensive applications of extruded products in the building trades are forecast.

Extrusion was used by Eichengrün<sup>30</sup> to form a porous mass which was dried to a dry brittle powder suitable for molding. He has extruded a highly heated viscous solution of cellulose esters or ethers, which may contain synthetic resins or other materials, through a narrow orifice so that the issuing mass swells and the solvent evaporates.

The production of strips or bands from synthetic resins in a continuous apparatus has been described by Schless.<sup>31</sup>

#### INJECTION MOLDING OR PRESSURE CASTING

The injection or forcing of a plastic material into a closed mold is also referred to as the "squirting" process, transfer molding, or erroneously as extrusion molding. In many ways it is similar to the die-casting of metals.<sup>32</sup>

In all types of compression molds the pressure on the material is produced indirectly by the closing of the press, but the distinguishing feature of the injection method is that the mold is closed first and pressure is then applied to the material to force it into place. Thus it is possible to produce much more complicated moldings with thin walls because there is always a high positive pressure on the stock. This is held to be one of its chief advantages. Jenkins<sup>33</sup> has stated that the injection process applied to cellulose plastics gives products of higher tensile strength than compression methods because of an orientation of the chain molecules which occurs during the operation. Similar effects are recognized in rubber and in tough synthetic resins, such as certain vinyl polymerization products, where it is well known that the strength and other physical properties vary with the direction and amount of flow produced in the molding process.

**Injection Molding of Permanently Thermoplastic Material.** Buchholz<sup>34</sup> has described a method of injection molding of thermoplastic materials. The preparation is placed in a feeding-device where it is softened by heat and is forced into the mold through a constricted heated passage which tends to improve its flowing characteristics. The mold is maintained at a temperature below the solidifying point of the material which consequently hardens very quickly. The machine described by Buchholz is quite complicated, using a hand wheel, a hand lever, foot lever and several springs. However, much simpler injection mechanisms operated by one control are now available.<sup>35</sup> Larger models are power operated, most of them being of the horizontal type.<sup>36</sup> An air-operated machine has been used for regular injection molding, requiring pressures of from 600 to 900 pounds.

Stadlinger<sup>37</sup> has discussed the commercial injection molding of cellulose acetate and vinyl resins, describing particularly the early work on cellulose acetate molding powders for use in compression molds. According to Stadlinger, it was Eichengrün<sup>38</sup> who first recognized the possibilities of the injection molding<sup>39</sup> of cellulose acetate compositions and who suggested that they were best adapted to small articles weighing less than 10 grams. Temperatures of 130-170°C. (260-330°F.) with pressures of 450-900 lbs. per sq. in. have been recommended for such work.

Vinyl resins were molded by injection as early as 1929 by Posner.<sup>40</sup> More recent processes<sup>41</sup> have suggested injection molding of polymerized indene and styrene as well as vinyl esters. It has been maintained that thermoplastic compositions<sup>42</sup> were handled by similar methods in France as early as 1918 and that over 90 per cent of the bituminous-base battery boxes manufactured there in 1930 were formed in this manner.

**Injection Molding of Thermosetting Resins.** Since thermoreactive resins have been extruded, it has also proved possible to inject such compositions in the same way that thermoplastic compounds are handled with, of course, the additional step of hot curing. The cure may be carried out in the injection press, or the molds may be charged and transferred to another machine for further treatment. Thermoreactive powders were first molded by injection in 1930<sup>43</sup> and a special type of phenolic molding powder was described at that time<sup>44</sup> which was reported to eliminate "working" or polymerizing after treatment, as this composition was said to be incapable of reaching the "C" stage. No special equipment

<sup>43</sup> *Ibid.*, 1930, 2, 66.

<sup>44</sup> *Ibid.*, 1930, 2, 52.

is required<sup>45</sup> as the injection cylinder and piston may be made as part of the mold. Chase,<sup>46</sup> and Hessen<sup>47</sup> have published further details of the operation.

Temperatures in this process range from 80-100°C. (170-212°F.) and pressures of 8500-14,000 lbs. per sq. in. fill the molds in approximately 15 seconds so that they may be removed and the cure completed in a hot press at about 1000 lbs. per sq. in. The time of cure is given as about 30-50 seconds per mm. (0.75-1.25 sec. per thousandth of an inch) of thickness at a mold temperature of 100°C. When the material is heated to the molding temperature as it is injected, Chase<sup>48</sup> found that thick parts cured more quickly than when compression molding is used. Special equipment<sup>49</sup> and special preparations<sup>50</sup> have been developed to meet various requirements.

Larger articles are now made by injection, especially where thin or complicated sections are called for, or where metal inserts are delicate and must be located exactly. These include twelve-cylinder automobile distributor covers<sup>51</sup> and manometer cases<sup>52</sup> over 15 inches long with molded threads at top and bottom.

Marble- and wood-effects are obtained by the injection molding of trays, smoking jars, ash trays and the like, using mixtures of several colors<sup>53</sup> introduced simultaneously through each of several inlets. For example, a tray 10 inches in diameter is made by employing three inlet ports in the base, located on a circle about five inches in diameter.

**Other Injection and Related Processes.** Synthetic resins have been used to impregnate containers molded of fibrous materials.<sup>54</sup> The resin is injected into a mold and heated until cured.

Kline<sup>55</sup> has stated that the interstices between the fibers in hot-molded products could be filled by forcing in a binder at pressures up to 500 pounds per sq. in. and temperatures of about 170°C., adding a solvent if necessary to secure penetration. The binder is subsequently cured by further heat. Gwaltney<sup>56</sup> has suggested that layers of sheet material could be cemented by a heat-hardened binder and the surfaces and outer layers of the sheets given a satin-like finish by using a hot pressure plate which had been plated with chromium.

Sauerbrey<sup>57</sup> has described a process for molding various materials by injection then subjecting the plastic mass to further pressure during hardening without further heating.

<sup>45</sup> *Ibid.*, 1930, 2, 296. An eighteen-cavity mold for tooth-brush handles is illustrated, and its operation with a cooperating cylinder and piston is described, charging three molds from the same plunger and piston, and finishing the cure in a separate press. All eighteen cavities are charged at once, each through two injection holes or inlets matching with outlets from the cylinder. Two or more holes are preferred to insure good mixing in the piece, and in general the more delicate the molding the smaller the inlet holes or nozzles should be. See also *ibid.*, 1933, 5, 71.

<sup>46</sup> H. Chase, *British Plastics*, 1933, 5, 29.

<sup>47</sup> R. Hessen, *British P.* 387,207, 1932, to A. Nowack A-G; *Brit. Chem. Abs.* B, 1933, 357.

<sup>48</sup> H. Chase, *British Plastics*, 1933, 5, 29.

<sup>49</sup> A double-acting hydraulic press is shown (*British Plastics*, 1931, 2, 574) and reference is made to direct-heated molds with flexible connections to allow a continuous cycle of injection, curing in a second press, cooling and stripping. Mold diameter should be about equal to the diameter of the injection ram. The most popular German machine (C. Stark, *British Plastics*, 1932, 4, 104) operates by air pressure reduced to 450 pounds from an initial pressure of 900 pounds per sq. in. A German mechanical press (Stark) uses a flywheel to generate the pressure for injection.

<sup>50</sup> "Ronisol" (phenol-formaldehyde) and "Ronilac" (urea-formaldehyde) molding compositions are used for injection molding in France (*British Plastics*, 1931, 2, 574; *Plastics and Molded Products*, 1932, 8, 239). They are available in three degrees of hardness, in all colors including white, for special purposes requiring high dielectric, mechanical, acid or heat resistance, and as odorless phenolic compositions for perfumery. The materials are usually softened at 100°C. and transferred to the injection cylinder at 60°C. (140°F.), at which temperature they will not cure even in an abnormally long time.

<sup>51</sup> For other developments in France, see *British Plastics*, 1931, 2, 574.

## PRACTICAL GENERAL MOLDING PROBLEMS

While various methods of molding have been described, there are a number of common difficulties that may be anticipated, typical of which is adhesion of the molded piece with subsequent breakage and difficulty of removal. Molding is an art, and experience is the best guide in meeting the many practical questions which arise. Each new mold and each new material may require some slight change in the method of handling. A few general rules can be given, however, with the hope that they will help to forestall the problems which may be expected.

**Sticking and Staining.** In the production of high-grade molded products difficulty may arise due to pieces sticking to the mold or due to the appearance of stains, discoloration or roughened areas on the finished articles. These two defects will be discussed together, since frequently in an attempt to overcome one problem, there will be a compensating trouble from the other. It is of utmost importance for best results to have a mold which is properly made, finished and polished. This should go without saying, but it is often responsible for a poor product. Next, and equally axiomatic, the mold must be clean and bright with a thin film of lubricant to prevent sticking. Scratches, roughness or dirt of any kind on the mold may be difficult to detect, and yet be sufficient to cause dirty pieces. For example, pencil marks on the mold are barely visible, but when a molding is made they are transferred to the piece and become very noticeable. On the other hand, the mold surfaces should not be chemically clean as this tends to cause adhesion. For best results a thin, continuous, invisible film of some lubricant, either applied separately as a "dope" or included in the composition itself, must be present. If this coating is removed, as by a solvent, sticking often occurs until it is replaced. However, too thick a film or one of the wrong kind will cause discoloration. This trouble may result from a number of causes, and may appear suddenly or gradually. Occasionally a stain will build up on the mold without showing on the piece until several have been molded. In the extreme case an oily smear may cover the whole piece so that it appears wet when removed from the mold.

**Chemical Sticking and Staining.** The question of chemical reaction between the metal of the mold and molding powder is important, especially in a new problem. Corrosion will prevent the formation of an adequate lubricating film, leading to serious sticking troubles, and, if severe, the mold may be etched beyond repair. Machine steel is the most common material but it cannot be used with thiourea-aldehyde resins or others containing large amounts of reactive sulphur as these compounds attack the hot mold, darkening and roughening it, thereby causing sticking and staining of the piece. The same result occurs when vinyl chloride resins are molded at high temperatures in copper or nickel molds, or when rubber containing sulphur is molded against copper, a combination actually used commercially to produce a permanent bond of rubber on metal.

Corrosion-resistant metals are required to meet special conditions.<sup>48</sup> Molds of stainless steel containing 14-18 per cent chromium are used to some extent, but these are expensive and more difficult to make than standard steel molds, and cannot be readily hardened. Chromium plating of molds for synthetic materials has been recommended and described at length by McKay.<sup>49</sup> Richardson<sup>50</sup> has recom-

<sup>48</sup> Metals suitable for use in molds are described in Chapter 67 from a mechanical standpoint.

<sup>49</sup> M. H. McKay, *Plastics and Molded Products*, 1931, 7, 552.

<sup>50</sup> F. E. Richardson, *Rubber Age*, 1928, 23, 607; *Chem. Abs.*, 1928, 22, 4272.

mended it for rubber and Mason<sup>61</sup> has referred to the successful use of this coating for both abrasion and corrosion resistance. The surface is, of course, very hard and smooth and can be used with most molding compositions, including those from thiourea, vinyl resins and rubber. Duralumin alloys<sup>62</sup> have also been used in molding hard rubber to prevent corrosion.

**Mechanical Sticking and Staining.** The degrees of sticking vary widely. Adhesion may cause only slight inconvenience in removing the piece, in no way damaging it or staining the mold, or separation may be almost impossible, resulting in a rough or a chipped piece or ruined form. Careful examination and study will often save much time in locating the cause of trouble. Repeated sticking or chipping in one place is often due to a slight defect in the mold, such as a scratch, dirt spot, or under-cut. In such cases the remedy is obvious.

Sticking and staining over larger areas, especially when there is variation in size or location, is usually caused by the composition or the method of molding. This indicates either that the necessary thin film of lubricant has not been built up, as in new or recently cleaned molds, that the film has been destroyed by excessive heat, or that the lubricant is unevenly distributed in the composition.

The use of too high a molding temperature will sometimes cause sticking and staining, as will also undercuring, or removing a thermoreactive composition before it has sufficiently hardened. Adhesion may also occur from too much cooling before stripping, especially of shellac and other compositions which are very brittle when cold. Rapid manipulation will usually help to overcome this trouble.

Thermosetting materials sometimes stick or show stains because pressure is applied at the wrong time or rate. If it is applied too rapidly staining is likely, whereas if the material is allowed to soften and then become infusible under heat without full pressure, staining accompanied by fine lines on the surface often occurs. This is the reason that fast-curing compounds cannot be used in making moldings requiring a protracted period of flow.

**Remedies for Sticking.** Since sticking is usually caused by the absence of a proper lubricating film between the mold and the molded piece, it can often be eliminated by a lubricant applied either directly or incorporated with the composition. The manufacturer of molding preparations always includes some agent of this type in his product, but the molder can easily add more if necessary. If sticking still persists, light machine oil, olive oil or common soap dissolved in water may be used to form a thin coating on the mold. Gasoline has been found helpful in the case of thermoplastic preparations made largely of shellac. Extremely small amounts must remain on the mold if staining or spotting is to be eliminated, however. A water-soluble sodium sulphonate compound obtained from mineral oil has been suggested to be useful as a mold lubricant<sup>63</sup> and certain solid lubricants (stearic acid, paraffin, ceresin and carnauba wax) have also been found to be of value. Dusting the mold with a finely powdered water-insoluble soap,<sup>64</sup> for example, zinc stearate or aluminum palmitate, has also been found efficacious. These compositions can be suspended in water by first wetting with alcohol to form a paste, and then diluting with water to form a solution to be used as a mold dope. Tallman<sup>65</sup> has applied aluminum stearate dispersed in a baked japan

<sup>65</sup> A. P. Tallman, U. S. P. 1,682,213, Dec. 13, 1928.

to molds used for rubber. Edison<sup>66</sup> suggested gilsonite or other asphalt in a volatile solvent (naphtha) as a lubricant in similar work.

Manufacturers of molding compositions have studied this problem extensively and have overcome sticking to a great extent by the inclusion of film-forming lubricants in the material. Stearic acid particularly is utilized for this purpose. Huxham<sup>67</sup> suggested the incorporation of zinc stearate or aluminum palmitate directly in the preparation and this addition has been very helpful in preventing sticking of materials which would otherwise cause serious difficulty, for example, those containing a reactive phenol-furfural resin as a binder. The addition of water-insoluble soaps may be made to the resin or to the composition at any stage in its manufacture, or they may be precipitated on the filler. An effective method is to grind the metallic soap with the otherwise finished molding composition in such a manner that each particle becomes coated with the finely ground lubricant. The distribution must be uniform and an excess avoided.

Another material, recommended by Cherry and Kurath<sup>68</sup> for use in hot-molded articles, is the dark brown, waxy reaction product of stearic acid, aniline and either formaldehyde or furfural. A method suitable for large, rough-finished articles consists in coating the mold with a material which decomposes at the temperature used. For example, a resin-asbestos mixture may be cast in an iron mold lined with paper previously treated with acid sodium sulphate solution and dried.<sup>69</sup>

**Remedies for Staining.** Staining is by its very nature hard to overcome, because it is often caused by the presence of a substance incompatible with the resins under the conditions of operation. The manufacturer can control the ingredients but once a material is added it cannot be removed. The molder, therefore, must resort to dilution of the objectionable component by blending, that is the addition of other stock free from staining action. Thus, the operator who encounters staining can only dilute an unsatisfactory material, or change his pressing technic until the trouble is overcome or the material used up. Lower temperatures and longer cures should be tried, and the time of applying pressure should be varied. If the composition has been exposed to moisture, re-drying may be of value. A variety of operation adjustments should be considered as sometimes very small changes in manipulation are efficacious.

**Blistering.** Blisters in molded articles are produced by the expansion of gases or vapors formed or liberated during the molding operation. They may be small and distributed throughout the article or may unite into one or two large defects well below the surface. In any event, the appearance and strength of the product are seriously altered. With permanently fusible compositions, blisters are usually caused either by molding at too high a temperature or by opening the mold before it has been sufficiently cooled. If blistering continues after adjusting these two factors, the composition should be examined, since it may contain moisture or solvents used in its preparation, and further drying is needed to eliminate the difficulty.

When molding thermosetting or reactive phenolic resin compositions at a temperature not exceeding 350°F. (177°C.), blistering is not likely to be caused by improper treatment but is more often traceable to the presence of solvents or moisture. On the other hand, excessively high molding temperatures and subsequent opening of molds without any cooling may cause blistering. The use of a cooling press adds one more step to the procedure and should be unnecessary with

<sup>68</sup> O. A. Cherry and F. Kurath, U. S. P. 1,898,069, Feb. 7, 1933, to Economy Fuse & Mfg. Co.; *Chem. Abs.*, 1933, 27, 2841.

<sup>69</sup> German P. 528,447, 1929, to Säureschutz-Ges.m.b.H.; *Chem. Abs.*, 1931, 25, 4139.

thermosetting compositions when the platen temperature is maintained within the usual range. Pieces requiring accurate sizing are an exception, since they tend to warp and vary in dimensions unless cooled under pressure.

In molding thermoplastic goods, it sometimes happens that a blister, containing gas under high pressure, forms near the surface. When removed from the mold the gas pressure fractures the material and blows out a piece of stock, leaving a hole with a little pit at the bottom where the gas was compressed. Such blow-outs generally occur shortly after removal of the article, but small raised blisters may continue to appear for a number of hours or even days after pressing, making inspection very difficult.

If pressings are made from a composition in sheet form, there is danger of folding or trapping air in the stock. This is particularly common with very adhesive materials and may even be caused by air originally trapped in the stock during the initial mixing, sheeting or calendering operation.<sup>70</sup>

**Heat Marks. Undulated Surface.** A rippled or uneven surface on molded articles made from compositions which become infusible on heating is attributed by some observers to the evolution of gases which form pockets between the mold surface and the material which is being molded. These very slight undulations are readily visible when the article is examined by reflected light. Whatever may be their cause, it is generally understood among molders that chilling the mold before opening will usually remedy the fault. Furthermore, this defect is not considered a serious one and the purchaser is often willing to condone a slight unevenness of surface to avoid the extra expense because of time taken in chilling the article. The author has observed the formation of this undulating surface in molding compositions having binders of a number of different kinds, including phenol-formaldehyde, urea-formaldehyde, acetone-formaldehyde and numerous other condensation resins.

With thermoplastic materials, heat marks may be much more serious. In some cases where too high a temperature or too long a heating period has been used, the preparation may flow out of a flash mold to such a degree that contraction occurs, leaving low spots sometimes an inch or more long. Reduction in heat will usually overcome this, and if the stock is heated before being placed in the molds, the treatment often suffices to permit a reduction in the temperature of molding.

Local heating or cooling may be necessary in certain cases. Sherts<sup>71</sup> has used this method to eliminate heat marks in molding cellulose acetate or nitrate into such articles as toothbrush handles. At the temperatures necessary to get good cutting-off of the flash at the edges of the mold he found that heat marks occurred only on the flat surfaces, and accordingly constructed small cooling channels near these surfaces.

**Control of Flow and Flow Marks.** Most thermosetting preparations are now available in several grades of hardness or flowing characteristics to meet the demands of the different kinds of molding. In general, the hardest grade that will give sufficient flow should be used. If the material is not sufficiently plastic at the given temperature of molding used, flow marks may appear. These are periodic, light and dark, cirrus-like markings in the finished article at right angles to the direction of flow. The composition may not be hot enough to flow under the pressure applied or it may have lost its plasticity through reaction caused by heat alone. This occurs with thermosetting compositions when preforms are improperly heated. Sheet stock which has been allowed to react too long will often show seams where pieces of the material have welded together. Careful preheating and

<sup>70</sup> Chapter 65 describes methods of eliminating air during mixing.

<sup>71</sup> J. H. Sherts, U. S. P. 1,819,444, Aug. 13, 1931, to Du Pont Viscoloid Co.; *Plastics and Molded Products*, 1932, 8, 114.

adjustment of the temperature and pressure in molding should eliminate this difficulty unless the composition is defective.

The flow of thermoplastic materials can be controlled by the temperature of molding and the timing. The stock temperature, the mold temperature, the time before cooling is started, and the final cooling temperature can all be varied. Tough preparations, such as cellulose acetate and certain vinyl resins, require a longer time to flow before cooling than do softer compositions having greater mobility at molding temperatures, such as shellac.

Flow marks of a different kind occur in the molding of transparent and translucent materials, especially where a filler or other substances capable of orientation are present. These defects are parallel to the direction of flow and are very diffi-

FIG. 194.—Tumbling Barrels Remove the "Flash" or "Fins" Where the Mold Sections Come Together.

cult to eliminate entirely, but slower closing of the press or working at a higher temperature sometimes helps.

Waviness occasionally appears after stripping articles containing coarse fillers, such as long-fiber asbestos or rough fabric. The trouble may at times be caused by incomplete impregnation of the filler, and at others by strains around the particles. The grain of a paper will often show through a thin resin coating even when the fiber is thoroughly saturated. Exposure to water emphasizes these effects particularly when a non-waterproof filler is present.

**Finishing of Molded Articles.** The finishing and inspection room of the molding shop should be equipped with lathes, buffing wheels, polishing wheels and a variety of abrasives. Buffing wheels for this purpose are generally made of canvas or sheeting, sometimes treated with a sharp cutting abrasive for what is termed a "hard wheel." A very mild abrasive or grease alone gives a "soft wheel." A twelve-inch buff running at 1800 r.p.m. and having a surface speed of about 5700 feet per minute can be regarded as standard practice. Perhaps the most important task of the finishing room is the removal of fin or flash to leave as

little trace of these irregular projections on the molded article as possible. If the product is round it may be placed in a lathe and a file lightly applied to trim off the fin and leave a smooth surface, but light flash in an accessible position may be removed by buffing or by a sandpaper belt. In a few cases the operator must resort to filing by hand. This is usually necessary only with odd-shaped pieces but in general the practice in molding is to make the fin as thin as possible to minimize the labor in finishing. The fusible or shellac type of molded articles are polished on a soft wheel which is greased but has no abrasive. Here again if the product is round it may be possible to construct some sort of holder to allow lathe polishing. Infusible compositions are usually buffed on a hard wheel with tripoli, followed by polishing on a soft wheel which carries no abrasive. Inserts occasionally need to be machined after the article has been molded, an operation which is best done before buffing and polishing.

Finishing of small articles, including the removal of flash, is frequently satisfactorily accomplished by placing them in a tumbling barrel which rotates at slow speed and allows the pieces to rub against each other or against other objects placed there for that purpose. (See Fig. 194.) Considerable time is required, but a great many pieces may be treated simultaneously. Special polishing compounds are sometimes added in the tumbling barrel. Open-work tumblers are frequently used which allow the flash to fall through onto the floor as it is removed.

An "ashing" treatment used in finishing cast resins consists of wet-buffing with ashes or other soft abrasive and water. A "coloring" process used on some colored plastics (celluloid and cellulose acetate) applies lime and grease on a buffing wheel following tripoli or rouge.

**Inspection.** The inspection department is responsible for the quality of the product, and may make any tests necessary to insure this, varying from a casual observation as the goods are being packed for shipment to careful dimensional checks on every piece. Examination may be made of all articles, of hourly samples from each press or of representative specimens from the whole press room. The important points may be dimensions, location of inserts, waterproofness, flatness and freedom from small blemishes or polish of the surface. The list could be extended indefinitely. The final operations are packing and shipping.

**Costs and Cost Estimating.** The detailed methods of cost finding and cost estimating are obviously not within the scope of this book, but an appreciation of their importance and relation to the chemistry and chemical engineering of synthetic resins is most desirable. In fact, the question of expense is emphasized by Bender<sup>72</sup> as the point at which most new resins fail and the engineer on practical molding work is usually required to spend much of his time in attempts to reduce costs.

When a very few pieces are made the mold costs are high, although some companies are said to have found it profitable to build a complicated mold for as few as 200 impressions.<sup>73</sup> With hand molds and slow pressing cycles, labor costs are predominant. The development of semi- and fully-automatic machines has gone through the stage of excessive machine costs and now the material cost is one of the most important items as mechanical improvements have greatly increased the

<sup>72</sup> H. L. Bender, *Plastic Products*, 1933, 9, 106.

<sup>73</sup> Arrangements for loan, rental or exchange of molds have been proposed in attempts to distribute the mold costs among several users and prevent needless duplication. *Plastics and Molded Products* published in 1932 and 1933 (8, 422, 431, 459) give information on certain stock molds owned by various molders. Small orders of parts from these molds are accepted. A Central Bureau for molds has been established in Germany jointly by Siemens-Schuckertwerke A.-G. and H. Rommler A.-G., of Berlin-Spremburg. This is known as the Matrice Center, according to *British Plastics*, 1933, 4, 543, and has several thousand different molds available to the participating companies as required.

rate of production. This means that any saving made in the cost of raw materials is quickly reflected in that of finished articles.

An estimating sheet for the total cost of a molding has been prepared by Rowell<sup>74</sup> and methods of costing are discussed by Spall.<sup>75</sup> Quigley<sup>76</sup> considered mold costs with particular reference to the proper allocation of overhead charges, and has estimated the percentage of material lost from various causes in the average molding plant. The possible reuse of flash and ground rejects is of course an important item in this connection, and practice in this respect varies widely with local conditions in each plant.

#### SPECIAL METHODS AND PROCEDURES IN MOLDING

**Molding of Light-Colored Goods.** The demand for color in many of the articles of our everyday life has been met by the molding industry with an ever-increasing range, brilliance and permanence of colored compositions, especially in the lighter pastel shades. This has made it necessary to keep each color separate and free from contamination by darker preparations and any other discoloring agent. The molding industry has become, perforce, one of the clean trades, for even dust in the air can easily damage the lighter shades. All equipment used in preparing or handling the powders in any way, including preforming machines, must be capable of a quick, thorough cleaning, or, failing this, must be reserved for one color or one group of colors only. Urea-formaldehyde compositions require special care in preparation and handling because the market demands these in very delicate tints.

**Molding Radio Tube Bases.** This is a very specialized product made now by only a very few molding companies that have developed the necessary auxiliary equipment to make bases at the low price prevailing. Large, multiple-cavity molds are employed,<sup>77</sup> being loaded simultaneously with ball preforms. Hollow contact pins are commonly used, molded into the base in such a way as to leave an open hole through which the connecting wires may be passed.

**Forming Large Structures of Synthetic Resins.** Comparatively large moldings have been made with the regulation steel molds and presses. For example, bedsteads<sup>78</sup> (24 lbs.) have been formed in a mold (2½ tons) but because of the size and the large amount of material to be heated, the molding step is very slow, allowing the production of but four pieces per hour. A large tank,<sup>79</sup> 4 lbs. heavier than the bedstead, has been similarly press-molded. Radio cabinets 22 inches high, weighing about 10 pounds have been molded of phenol-formaldehyde composition in an eight-minute cycle.<sup>80</sup>

Acid-proof compositions of phenol-aldehyde resins and asbestos fillers (Haveg) have been developed to the point where large structures can be built for use in industry, providing chemically resistant tanks, agitators, pipes, trays, filter press plates and the like. Tanks up to 10 feet in diameter and 10 feet high can be made in one piece without seams. These are built up in forms from the resin-filler mixture in a condition much like cement or plaster, and are then hardened by means of heat. Methods of joining such sections to make large composite vessels have been described by Wirth,<sup>81</sup> who made acid-proof structures by cementing

<sup>78</sup> *British Plastics*, 1931, 3, 198. See also corrections, *ibid.*, 1932, 3, 396. The mold was made in a number of separate parts, hardened and then assembled.

<sup>79</sup> *British Plastics*, 1932, 3, 396. The mold weighed over 2½ tons.

<sup>80</sup> These were molded in a 850-ton press. Each half of the mold was built from one piece of steel, and then hardened.

<sup>81</sup> J. K. Wirth, U. S. P. 1,747,964, Feb. 18, 1930, and 1,789,642, Jan. 20, 1931.

together building elements with an adhesive or binder which hardens at room temperatures.<sup>82</sup> In Australia, plastic compositions have been used to make pipe<sup>83</sup> from 3 inches to 120 inches in diameter and up to 12 feet long for use as water mains and other general piping applications.

Large press moldings made from vinyl resin compositions have been described by Davidson and McClure.<sup>84</sup> These are panels 2 inches thick by 2½ feet wide and 8½ feet long, weighing 150 pounds. When used as wall sections they showed no tendency to warp or crack over a period of one year. Davidson and McClure have reported that a low degree of shrinkage occurs when vinyl resin is used and that, as compared particularly with curing resins, fewer strains are set up in the molded article. In one example which they have described, a layer of vinyl resin composition was molded over a porous sound-insulating and deadening core that had sufficient crushing resistance to withstand the molding pressure of 250 pounds per square inch. A very simple, makeshift mold was used, consisting of two aluminum plates and removable steel strips which formed a ring around the edges. The upper plate entered this ring about 0.5 inch when the mold was closed, thus forming a semi-positive mold. A layer of molding composition was spread evenly in the bottom of the mold, the core placed carefully in position with 0.5 inch clearance all around, and more molding composition added until the mold was fully charged. Steam was used to heat both the mold and the composition. Even with these crude conditions practically all of the panels formed were satisfactory for use.

**Methods of Ornamenting.** Variegated products have been made from plastic compositions by introducing flexible materials such as fabric, paper, leaves of trees, metal sheets with figured designs, wire or threads before the mass has set into final condition.<sup>85</sup> Lumps of synthetic resin have been covered with differently colored adhesives and molded to produce a veined effect.<sup>86</sup> Murphy and Owen<sup>87</sup> have decorated rubber or other materials, including synthetic resins, by coagulating emulsions or dispersions of rubber, gelatin or synthetic resins on their surfaces. The designs formed are irregular and may resemble leather. Dennis<sup>88</sup> has described the use of synthetic resins or casein for making molded ceiling roses or globes for electric lamps. Plates and other articles of synthetic resin are ornamented or modified by applying a mixture of a natural or synthetic resin and a filler with or without a pigment,<sup>89</sup> using pressure and heat to unite the powder layer with the surface of the article. Thompson<sup>90</sup> has treated rubber by imbedding globules (less than 1 mm. in diameter) of wholly or partly transparent material in its surface. Single<sup>91</sup> has also molded plastic articles bearing surface designs.

Decorative overlays, for example of cellulose acetate, may be applied to thermoplastic articles and welded in place by heat and pressure. These overlays should have lower plasticity than the base material.<sup>92</sup>

Urea-formaldehyde resin products have been embellished by Froese<sup>93</sup> to give

a dark, sunken design surrounded by a lighter, raised border where the natural color has been bleached out of the resin composition. The result is accomplished by stamping or branding the surface for about four seconds with a metal die heated to a temperature ranging from 1000-1200°F. The brand should be shaped to fit the surface of the object. The burning or scorching forms the design in intaglio and at the same time darkens the material. At the edges the heat swells and bleaches the composition.

**Miscellaneous Procedures.** Mention should be made of water emulsions of synthetic resins, and their uses. Concentrations up to about 50 per cent of phenol-formaldehyde resins are available. These dispersions of resin in water have been used to make molding compositions, for example, with wood flour or sawdust. The filler is dampened with a dilute emulsion and the resin coagulated on the filler as the latter absorbs the water. Low-grade semi-porous moldings can be made from the dried filler with very much lower resin content than that in standard molding powders.

Emulsions may also be used in the preparation of sponge materials from resins by processes similar to those used in preparing sponge rubber from latex or artificial dispersions of rubber in water.<sup>94</sup> Porous sheets of rubber or synthetic resin compositions suitable for storage-battery separators have been made in this manner. A mechanical method for making these consists in piercing sheets of the uncured material with fine perforations and subsequently hardening by heat treatment.<sup>95</sup> Synthetic resin compositions containing a filler are used for connecting different parts of electric insulators.<sup>96</sup>

Hollow articles have been molded from synthetic resin powder by Ireland,<sup>97</sup> using fusible metal cores. Bray<sup>98</sup> has molded thin-walled sections, assembled these to form a hollow core, and introduced molding material to make a hollow article of which the core member forms a permanent part. Novotny<sup>99</sup> has suggested placing a potentially reactive resin mass around a core of a solidified gas, such as solid carbon dioxide, applying heat and pressure to gasify the core and cure the resin, producing a hollow article of the form desired.

Dillehay<sup>100</sup> modified the outside of bituminous composition moldings by rolling a charge of a plastic material (asphalt-filler mixture) in a molding powder containing a condensation resin to form a coating on the mass before molding.

A liquid mass of synthetic resin may be provided with resistance wires and the resin hardened by passing an electric current through the wires.<sup>101</sup> Hora<sup>102</sup> molded sliding-clasp fasteners for cloth in such a way as to allow attaching them to the fabric at the time of molding.

#### PHONOGRAPH RECORD MOLDING

The materials and methods used in the molding or pressing of phonograph records<sup>103</sup> show the changes which have been taking place in this industry. Some of

<sup>103</sup> C. W. Rivise (*Plastics*, 1930, 6, 137, 155, 213, 277, 334, 397, 455) gave a review of 47 U. S.

the factors that have at last made synthetic resins competitors of the long-established shellac compositions will be indicated.

Phonograph records have been made from shellac since the early days of commercial production, when the compositions, then used for button manufacture and other moldings,<sup>104</sup> were found to make satisfactory records. So much shellac has been used by the record industry that for years this has been the controlling factor in its price. Many other materials, especially natural and synthetic resins, had been tried and used to some extent in records, but for the most part they were merely substitutes for shellac and did not contribute much to the art, either in quality of the record or quantity used. Since 1931 synthetic resins and cellulose derivatives,<sup>105</sup> including cellulose xanthate,<sup>106</sup> have been used for producing special records which are superior to shellac records in certain respects although they cost more to manufacture. Further extension is apparently largely dependent upon price and other commercial aspects rather than technical considerations.

The predominance of shellac in record manufacture for over thirty years is based on its peculiar advantages and on some other circumstances which will be mentioned briefly. Although far from perfect, it combines toughness, flow, and heat stability with hardness and sufficient water resistance to a greater degree than any other natural resin. The industry has developed methods which minimize its disadvantages, and which have been called "the high-water mark of molding technic."<sup>107</sup> Other materials with inferior molding qualities were not considered even if cheaper or better in some other way. The fact that shellac compositions could be reworked placed the curing resins at a disadvantageous price level which was further increased by the short molding time of the former. The large investment in stocks of shellac, necessitated by the time required for shipment from India, and in special equipment for handling, reduced the interest in any development which might jeopardize these investments. Furthermore, the acoustics of the old phonographs were so poor that they could not reproduce faithfully with the old records and would not give appreciably better results with the modern records. The introduction of the electric phonograph was the ruling cause of record improvement.

**Shellac Substitutes.** Repeated attempts have been made to use practically every plastic or resinous material for records, either alone or with shellac. All of the natural and fossil resins were tried without success except that small amounts have been used as plasticizers. Pitch from the destructive distillation of hardwood is used in cheap records, sometimes in considerable quantity, but gives rise to an inferior product. Permanently fusible acetaldehyde condensation resins have been tried but they cannot be used alone because of low melting point or lack of toughness. The same is true of fusible phenol-formaldehyde and alkyd resins. So-called nonbreakable records have been made to overcome the brittleness of shellac. For example, coal-tar pitch has been used as the chief impregnating material for paper pulp sheets which are united by heat and pressure into an unbreakable, though thermoplastic, record with a thin shellac composition surface. Thick records with a thin surface layer of phenol-formaldehyde resin<sup>108</sup> and a center

and 20 foreign patents relative to records. H. C. Bryson (*British Plastics*, 1929, 1, 187; 1930, 1, 326, 442, 484, 539) described general processes from recording to shipping. H. C. Bryson (*British Plastics*, 1931, 3, 104, 160, 223, 259) also discussed phonograph records in general, including new developments. In a later article (*J.S.C.I.*, 1932, 52, 495) he discussed various kinds of non-breakable records.

<sup>108</sup> L. H. Bakeland, U. S. P. 1,053,264, Dec. 30, 1913, to General Bakelite Co. This covers a

layer about one-quarter of an inch thick made of paper or cardboard impregnated with a cheap mixture of resins have been marketed. This record was unbreakable, but it was heavy and bulky and had such a short life that it is not now manufactured. Gelatin records have been proposed, especially with the addition of softening and preserving agents.<sup>100</sup>

Shellac-surfaced laminated records have been made successfully. Here cheap natural resins and some pitches are used as a core, but the surface layer and thus the playing characteristics of the record are practically identical with those of solid shellac.

**Improvements by the Use of Synthetic Resins.** Synthetic resin records are much better acoustically, since they have less "background" or "surface noise" and reproduce much louder passages with fidelity. This is believed to result from their ability to yield finer grained, stronger compositions. The synthetic resin records have better wearing qualities, lighter weight and greater flexibility, and are less subject to breakage and to deterioration by moist air because of their superior water-resistance.

Cellulose acetate compositions have been used chiefly in manufacturing thin transparent records, and in laminated records with printing or illustrations in black and white, or even in four colors, under the acetate surface. Laminated records with colored, but necessarily opaque, shellac surfaces have also appeared.

**Production Methods.** The production of phonograph records, as previously mentioned, is a very specialized art, developed and operated for many years by the other record companies with shellac as the base material. The practice has so influenced the manufacture of all types that the fabrication of solid shellac records will first be described, followed by the modifications illustrating various steps in the introduction of synthetic resins into this field.

**Solid Shellac Records.** The raw materials for the usual solid or non-laminated shellac record are shellac, manila and other copals, rosin, cotton flock, carbon and bone black, nigrosine dye,<sup>101</sup> and mineral fillers. Hardwood pitch is added in the cheaper records.

The filler most frequently used is a red clay which is an iron aluminum silicate containing considerable free silica. Fine slate flour<sup>102</sup> of somewhat similar composition may be used. Some manufacturers prefer rotten stone (tripoli) with either ground barytes or blanc fixe, a mixture most often used for laminated records. The high specific gravity of the barytes makes a solid record containing it very heavy.

Shellac is the main component, to which smaller quantities of the other resins are added. Flock is usually about 3 per cent of the total weight. The blacks may vary from 2 per cent to 15 per cent, depending upon which ones are used and on the color of the mineral filler. The latter ranges from 45-75 per cent of the mix by weight, depending upon the kind used, the higher percentage, of course, applying to very heavy fillers. All components must be very fine and free from grit or coarse, hard particles.

The ingredients are ground separately, screened to remove foreign materials, and lumps, and then weighed out in the proportions required. Ground record scrap, made by breaking and grinding rejected records and press-room flash, is

non-thermoplastic sound record embodying an infusible condensation product of phenols and formaldehyde and includes both solid and laminated records.

introduced at this point, and may constitute a considerable proportion of the mix. It is necessary to remove the paper labels from rejects before incorporation with the record composition. The dry powdered materials are thoroughly intermingled in the cold in a large mixer and small batches are weighed out for the grinding or milling operation. Either standard mill rolls or the larger enclosed Banbury mixers may be used.<sup>112</sup> The composition is ground for a short time at 100-105°C. (210-220°F.) until all lumps and unmixed material have been thoroughly dispersed. The hot plastic dough is now transferred as quickly as possible to "blanking" or calendaring rolls which form it into a long sheet while still hot. This sheet is marked into rectangles by rotating knives which cut it only part way through. When cold it is readily broken up into separate rectangular pieces, or "biscuits," each containing just enough material for one record.

**Pressing.** The type of press most used for solid records has a hinged, counter-balanced head. The cored steel flash-type dies are permanently attached, one section to the head of the press and the other below to the lower platen. The hydraulic ram is mounted in the body of the press and moves the lower platen and die upwards after the head of the press is lowered and locked in place. Each die contains a nickel-plated copper "matrix," made by electrolytic deposition on a wax blank containing the original recording.<sup>113</sup> The matrix is held in place by a ring which serves as the edge of the die and controls the thickness of the record. Matrices must be easily and quickly changed, especially when relatively few records of each kind are made.

The record molding operations were originally carried out by hand, but now, although the operations are the same, presses are used which are more or less automatic. The record molds are first heated by steam between 80-105°C. (175-220°F.), paper labels are placed in position on label pins, the hot soft stock from the steam table is placed in the center of the bottom matrix and the top of the press is closed and locked. The real pressing now starts as hydraulic pressure of about one ton per sq. in. of record surface is applied. The steam is turned off and cold water is passed through the same spiral channels in the mold blocks until the temperature drops to about 30-40°C. (85-105°F.). The hydraulic valve is then closed and the relief valve opened to drop the press. The head may now be raised and the record with its adhering flash removed. Cooling water is followed by steam, the relief valve closes, and the cycle is repeated. The operator removes the flash from each record while the next is in the press. Mechanical belt-driven toggle presses are used by some manufacturers, giving a pressure of about 1000 pounds per sq. in. The output varies with size and other conditions, but solid shellac records can be produced at a fair average rate of two per minute.

The records now go to the finishing lathe where the edges are smoothed and polished, either automatically or by hand. They are then wiped clean of dirt and dust, inspected visually and packed. Test records are played to detect any invisible defect.

**Laminated Records.** The laminated shellac record<sup>114</sup> has a thin surface layer of shellac composition coated on a paper disk which separates it from the cheap thermoplastic core. The surface material is similar to the solid record compositions except that it contains no flock. It is prepared in the same way, then ground to a fine powder and dusted onto the paper disks (slightly smaller than the finished record), which have previously been coated with a very heavy solution of shellac in alcohol. These are dried and pressed between hot rolls to com-

<sup>112</sup> See Chapter 65 for equipment and operation.

<sup>113</sup> B. A. Dimon, *Monthly Rev. Am. Electroplating Soc.*, 1932, 19, 7; *Chem. Abs.*, 1932, 26, 5501.

<sup>114</sup> H. C. Bryson, *J.S.C.I.*, 1933, 52, 495. R. Jones, *British Plastics*, 1932, 3, 357.

compact the material.<sup>115</sup> The core may contain coal-tar pitch, natural resins and sometimes a little linseed oil, together with cheap mineral fillers and usually some powdered mica to increase its strength. It is mixed and sheeted into biscuit as for solid records.

Pressing and finishing operations are very similar to those on solid records, except that a different type press may be used in which the two dies open like the covers of a book and are more accessible. The coated paper sheets or "spots" and the labels are placed in the press with the shellac sides toward the matrices. The softened core material is put in place between them just as for solid record pressing, and the same kind of a pressing cycle is used although a slightly longer cooling time is necessary because of the paper. Flash and rejected records, paper and all, are ground up and used again for the core.

Illustrated records with transparent surfaces may be made in the same way, except that a paper base and a transparent surface disk are used. Laminated records of this type have been proposed with cellulose acetate or nitrate surfaces on a cardboard instead of a plastic core, but have never come into extensive commercial use in the United States. Cellulose ester records with a cardboard base are more difficult to press than the plastic type, and rejected records are generally unfit for re-use.

**Vinyl Resin Records.** Vinyl resin records<sup>116</sup> made from the vinyl chloride resin with a small amount of vinyl acetate have had some commercial use in recent years. These are lighter, stronger and less brittle than shellac, and thus can be made much thinner. The finished record has low "scratch" or background noise and is less affected by the moisture of the air, because of the relatively better moisture-resistance of the resin and the absence of cotton flock, which is omitted as unnecessary because of the greater toughness of the resin itself. These advantages have allowed motion picture theatres to use twelve-inch vinyl resin records weighing four ounces each to replace the old standard sixteen-inch shellac records weighing twenty ounces. Shipping weight and breakage are both greatly reduced. Solid vinyl resin records have also replaced a laminated celluloid record with cardboard core, used for home recording. The new type not only avoids the possible fire hazard of celluloid, but appears to have better recording properties.

Vinyl resin compositions have a practical advantage in that they can be handled by the same equipment used for shellac with only minor changes in technique. Silica powder is used as a filler, in somewhat lower percentage than in shellac mixes. Fillers containing iron compounds cannot be used with vinyl chloride resins because of chemical reaction, although iron equipment causes no trouble. Mixing and pressing operations are conducted at slightly higher temperatures and are somewhat slower but otherwise they are similar to the procedure with shellac. Solid records are produced without cores, the resin remaining thermoplastic. Flash and rejects with label paper removed are worked back again into the mix just as with shellac, a very important factor in cost.

**Resorcinol Resin Records.** Records of heavy paper coated on one side with a resorcinol-formaldehyde resin composition<sup>117</sup> have also been used. They have always been made single faced because of the tendency of a double-coated sheet to blister during curing and the backs are waterproofed with lacquer to prevent

curling. This record is lighter, thinner and less fragile than the standard shellac record.

The resin is formed in solution, a silica filler is added, and the thick, adhesive mixture is coated continuously on the paper as it comes from rolls. The resin coat is dried in a hot-air dryer and the coated paper is cut into large sheets which are allowed to season. Several records are pressed on a sheet at one time in a modified printing press with a gas-heated platen and a very short operating cycle. Subsequently, label information is printed on the surface, the back is sealed with lacquer, and the records are cut out of the sheet ready for inspection.

## Chapter 69

### Testing of Laminated and Molded Materials

Test methods and specifications are vital to those interested in the applications of synthetic resins because of the multiplicity of plastic materials proposed for identical purposes. In this situation, since competing products may be entirely dissimilar with respect to chemical composition or details of manufacture, bases of comparison have necessarily been drawn to reveal the properties in which the consumer is most interested. Thus, the established standards are found to cover such factors as tensile strength, elasticity, dielectric constant, hardness, resistance to abrasion and other characteristics having particular reference to the type of service expected from the finished article. Molders, manufacturers of resins and consumers of their products have from time to time developed their own specialized methods of test, but generally these have differed so widely from each other in point of view that they are of doubtful value as bases for uniform specifications.

However, all such procedures have been considered and given their proper weight in the development of the present standards of the industry. The National Bureau of Standards early recognized the need for investigation of the electrical properties of phenol-aldehyde resins and conducted several important researches on the subject.<sup>1</sup> Later, commercial laboratories became interested in the subject and developed methods for determining the physical and chemical properties of their products to supplement electrical tests. The American Society for Testing Materials undertook the task of unifying the results of various investigators in the field and its reports are now accepted by the industry in the United States. The methods of test given in this and the following chapter are based as far as possible on its recommendations.

In Germany, the methods of the Verein Deutsche Elektrizität and the Allgemeine Elektrizitäts-Gesellschaft differ in detail from American practice, while in France, standards have been approved by the Union des Syndicats de l'Electricité and by the French public services.

#### PART I

##### TESTS OF SHEET LAMINATED MATERIAL

The standard tests of laminated materials were originally developed to reveal their properties as electrical insulators, since this was formerly the most important application. However, they are equally useful in evaluating laminated sheets used for other purposes. The American Society for Testing Materials<sup>2</sup> has published a series of tentative standards and methods which form the basis of the tests here given.

**Tensile Strength.** The tensile strength can be determined on any available testing machine, using the standard tensile strength test specimen. (See Fig.

<sup>1</sup> H. L. Curtis, *Bur. Standards Sci. Papers*, 1914, 234; *J. Wash. Acad.*, 1914, 4, 492; *Chem. Abs.*, 1915, 9, 178. J. H. Dillinger and J. L. Preston, *Bur. Standards Technol. Paper*, 1922, 216; *Chem. Abs.*, 1923, 17, 319.

<sup>2</sup> A.S.T.M. *Tentative Standards (D229-32T)*, 1932, 871.

195.) Since the strength of laminated materials frequently varies according to the direction of the grain in the sheet it is essential that specimens be cut both with and across the sheet and that this direction be clearly designated in reporting results. The unit value for tensile strength is calculated from the force required to break the piece divided by the cross-sectional area, based upon the dimensions found before testing.

**Modulus of Elasticity.** It is sometimes desirable to determine the modulus of elasticity, that is, the stress required to produce a unit distortion. This can be readily done by means of an extensometer, measuring the elongation of a convenient gaged length at the middle portion of the test specimen under various definite loads.

$$\text{Young's Modulus of Elasticity} = E = \frac{\text{Stress}}{\text{Strain}} = \frac{FL}{Ae}$$

$F$  is the force applied in pounds.

$A$  is the area of the cross section of the test specimen in inches.

$L$  is the gage length in inches over which elongation is measured.

$e$  is the elongation of the gage length in inches.

**Flexural Strength.** In determining flexural strength, the specimen is tested as a simple beam loaded at the center. The contact edges of the supports on

FIG. 195.—Tension Test Specimen for Laminated Sheet Insulating Materials.

which the specimen is placed are rounded to a radius of  $\frac{1}{8}$  inch for materials thicker than  $\frac{1}{8}$  inch, and to a radius of  $\frac{1}{16}$  inch for thinner materials. The distance between the points of support is 4 inches for edgewise tests of all thicknesses, and 8 times the nominal thickness of the material for tests in the flatwise direction, except that the minimum span is  $\frac{1}{2}$  inch. It is not recommended that tests be made in a flatwise direction for materials thinner than  $\frac{1}{32}$  inch, nor in an edgewise direction for materials thinner than  $\frac{1}{4}$  inch.

The specimen to be used flatwise is  $\frac{1}{2}$  inch in width unless the sheet is over  $\frac{1}{2}$  inch in thickness, in which case the width should be equal to the thickness. The latter dimension of the specimen is always the full thickness of the sheet from which the piece is cut. The length of the sample is 1 inch greater than the distance between the supports upon which it rests. As in the test for tensile

strength, specimens should be cut from the sheet both with and across the grain.

The maximum fiber stress in pounds per square inch is calculated from the flexural strength observations by the formula:

$$R = \frac{3PL}{2bd^2}$$

when:

*R* is the maximum fiber stress, or "Modulus of rupture" expressed in pounds per square inch.

*P* is the load in pounds.

*L* is the distance between the points of support in inches.

*b* is the width of the specimen in inches.

*d* is the thickness of the specimen in inches.

By observing the deflections of the specimen at the mid-point between the supports for different loads, the value of Young's modulus by bending can be calculated from the expression:

$$Y = 1/4 \frac{PL^3}{bd^3e}$$

when:

*Y* is Young's modulus for transverse loading.

*P* is the load on the bar at its mid-point in pounds producing the deflection of the mid-point *e* in inches.

*L*, *b*, and *d* have the same significance as in the expression for flexural strength.

**Compressive Strength.** In making tests for compressive strength a specimen in the form of a 1 inch cube is used for all materials which are 1 inch or greater in thickness. When it is desired to obtain the crushing strength of materials which are thinner than this, inch squares are cut and piled making a specimen at least 1 inch high. Materials thicker than 1 inch can be tested in either the flatwise or edgewise direction. However, sheets having thicknesses less than 1 inch are tested regularly in only one direction, that is, flatwise.

**Impact Strength.** The information to be obtained from the impact strength of materials is continually becoming of greater importance and has been reviewed by the American Society for Testing Materials.\* While these methods at the present time do not include tests on laminated materials, the same methods and apparatus can be readily used for such compositions, but a machine having a striking energy of 5 foot-pounds will be adequate for only the weakest laminated products. In order to cover the entire range of this class of materials 12-15 foot-pounds will be required. A specimen 0.5 inch by 0.5 inch by 2.5 inches will be satisfactory for the Izod test and one 0.5 inch by 0.5 inch by 5 inches for the Charpy test. (See Fig. 196.) The specimen may be notched or unnotched as desired, but care must be used in making comparisons between results obtained from the two types. It will be to advantage to confine control tests to one type of specimen. This is particularly true since the effect of the notch cannot be predicted with certainty. In determining the impact strength of laminated products the method will depend upon the thickness of the sample. Materials, either paper or cloth filled, having a thickness of  $\frac{1}{8}$  inch, may be tested either flatwise or edgewise. Specimens having a thickness of  $\frac{1}{8}$ - $\frac{1}{2}$  inch should be  $\frac{1}{2}$  inch wide, and of the same thickness as the original from which they are cut. The notch for laminated materials of  $\frac{1}{4}$  inch thickness or less, need only be 0.050 inch deep when the specimen is broken flatwise. When breaking edgewise, the standard notch of

\* A.S.T.M. Tentative Standards (D256-82T), 1933, 730.

0.100 inch should be used in all cases. In reporting the results the observer should specify the dimensions of the piece tested, the direction in which it was broken, whether it was notched or unnotched, and, if notched, the thickness back of the notch.

**Water-Absorption.** Since the absorption of water by laminated materials may have a very decided effect upon their mechanical and electrical properties, it is desirable to know something concerning their ability to resist such penetration.

FIG 196.  
Simple Beam (Charpy)  
Impact Machine.

The measure of their water-absorption properties is usually determined by exposure to high-humidity atmospheres or by immersing the materials in water. Such conditions are more severe than are actually found in service, but they do represent the extremes of exposure. Although the absorption of water weakens the electrical characteristics of these materials, a certain amount of water may improve their mechanical properties. Eventually, however, these also are impaired by an excessive water content.

(a) *Rate of Absorption.* A suitable specimen for use with laminated materials is a rectangular strip of the same thickness as the sheet and 1 inch wide by 3 inches long. The edges of the piece should be carefully smoothed with fine sandpaper. Before immersing the specimen in water, it is weighed and then conditioned by drying for an hour at a temperature of  $105 \pm 1^\circ\text{C}$ . and afterwards placed in a desiccator at room temperature to cool after which the loss in weight

due to drying may be determined. The dried specimen is then immersed in distilled water at a temperature of  $25 \pm 2^\circ$  and, after 2 hours immersion it is removed from the water, wiped dry with a cloth and weighed. It is replaced and, after a total of 24 hours immersion, it is again removed, wiped and weighed. The percentage of water absorbed during both intervals is calculated on the basis of the weight of the dried specimen.

(b) *Total Absorption at Saturation.* If the sample is over  $\frac{1}{16}$  inch thick, materials of good quality will require an extremely long time to become saturated. Therefore the specimen for the saturation test should be machined and finished to  $\frac{1}{16}$  inch by 1 inch by 3 inches. It is dried as outlined above and immersed in distilled water. At intervals of 24 hours the piece is removed from the water and weighed. The weighings are repeated every 24 hours for the first week and then at intervals of 1 week thereafter until a difference of less than 1 per cent is found between successive weighings. The total water absorbed is, of course, the difference between this saturated weight and the original dried weight. The rate of absorption of water by laminated materials has been determined by many experimenters but only a few data have been published. Leopold and Johnston<sup>1</sup> have, however, reported results obtained on Bakelite strips 42, 71 and 139 mm. thick when immersed in distilled water. The work indicated that the specimen 139 mm. thick would not become saturated for a period of years. This only applies to resins and not to laminated or molded materials as the latter will reach saturation within the course of a few weeks if the recommended thicknesses are used.

(c) *Effect of Temperature on Water-Absorption.* In determining the water-absorption of laminated materials, it is essential that the temperature of the liquid in which the samples are immersed be maintained practically constant, since the permeability is greatly affected by temperature differences. The manner in which the absorption varies with the temperature may be found by testing at three different temperatures,  $25 \pm 1^\circ\text{C}$ .,  $50 \pm 1^\circ\text{C}$ ., and  $75 \pm 1^\circ\text{C}$ . This is best done by placing the vessel containing the water and specimens in a thermostatically controlled bath or oven. The rate of absorption (a) and the total absorption (b) can also be determined under these conditions.

(d) *Absorption in Humid Atmospheres.* Although laminated materials are seldom exposed to working conditions which involve total immersion, there are many cases when the material is subjected for considerable periods to high humidities. Hence, it is sometimes of interest to know something about the absorption of moisture at various humidities. The specimens are prepared as indicated and are weighed after they have been conditioned. They are then placed in warm atmospheres, say  $35^\circ\text{C}$ ., of varying moisture content, such as 75 per cent, 90 per cent and 0 per cent relative humidity, for various periods and the percentage of absorbed moisture is calculated. The exposure is continued at the respective humidities until successive weighings at 24-hour intervals do not differ by as much as 1 per cent of the total variation during the test. The 75 per cent relative humidity can be obtained by a sodium chloride solution having an excess of salt present. The 90 per cent relative humidity can be secured by the use of an aqueous supersaturated potassium nitrate solution. To obtain a dry atmosphere, it is best to use one of the aluminum salts or phosphorus pentoxide rather than sulphuric acid as the slight fumes will react upon the laminated material to a certain extent. The temperature of  $35^\circ\text{C}$ . is chosen as it is rarely exceeded in a laboratory during the warmest seasons.

(e) *Percentage of Volatile Material.* The specimen is prepared in accordance with the methods suggested for the determination of the rate of water-absorption.

<sup>1</sup> H. G. Leopold and J. Johnston, *J. Phys. Chem.*, 1928, 32, 876; *Chem. Abs.*, 1928, 22, 3080.

The sample is weighed as prepared and then dried in an oven at a temperature of  $110 \pm 1^\circ\text{C}$ . in an identical manner, but the drying is continued until successive weighings taken at 24-hour intervals show differences of less than 1 per cent of the total decrease in weight. Before weighing, the specimen should be cooled in a desiccator at room temperature. The difference between the original weight and the dried weight is the volatile content of the material. This volatile content may consist of both water and solvent remaining from the manufacturing process.

**Dielectric Strength.** The dielectric strength of laminated materials may be determined at commercial frequencies by a short-time test, a 1-minute step-by-step test or by an endurance test.<sup>a</sup> By any of the methods a 2-kilowatt transformer is required if 50,000 volts are to be used, and if greater potentials are to be employed a 5-kilowatt transformer is necessary.

The short-time test consists in raising the voltage continuously at the rate of 500 volts per second until breakdown occurs. The step-by-step test starts with a potential less than that required for breakdown and the voltage is increased in accordance with Table 69.

TABLE 69.—*Step-by-Step Test.*

Value Found for Breakdown by Short-Time Test	Initial Voltage	Increment of Increase
12.5 KV or less	2 KV	0.5 KV
12.5-25 KV	6 KV	1.0 KV
25-50 KV	12 KV	2.0 KV
50-100 KV	30 KV	5.0 KV
Over 100 KV	40 KV	10.0 KV

The voltage is held at each step 1 minute and the change to the next step is made within 10 seconds, the process continuing until breakdown occurs.

The endurance test is made at a temperature of  $100^\circ\text{C}$ . A voltage equal to 10 per cent of the maximum potential applied in the short time test is maintained for 30 minutes. The voltage is then increased by steps equal to 20 per cent of this initial value until puncture occurs. Each value is held for 30 minutes.

The endurance test subjects the material to the most severe conditions to be encountered in service. It is, however, of such a protracted nature that frequently too much time and expense are involved. On the other hand, the short-time test is entirely too mild and depends largely upon the rate at which the voltage is raised as well as the capacity of the testing outfit. It is quite difficult for different observers to obtain comparable results with manually controlled apparatus. The step-by-step procedure is therefore recommended as the most practical test since it is sufficiently severe to bring out the differences between materials. If it is desired, the effect of temperature may be taken into account.

It has been customary to make tests on built-up materials at right angles to the plane of laminations. For materials not over  $\frac{1}{4}$  inch thick, the test piece should be about 6 inches square and the electrodes should be 2 inches in diameter with edges rounded to a radius of  $\frac{1}{4}$  inch. Results are most satisfactory if the work is done under oil. When the dielectric strength is over 400 volts per mm., it will be necessary to have a transformer of more than 100,000 volts capacity for pieces a quarter of an inch thick. If potentials are greater than 100,000 volts, it may also be necessary to employ larger specimens even when tested under oil in order to prevent sparking over the edge.

Comparisons of dielectric strength should not be made between values obtained on specimens of different thicknesses, since the thinner the material tested, the

<sup>a</sup> *A.S.T.M. Tentative Standards (D149-38T)*, 1932, 814.

higher will be the dielectric strength per unit of thickness. Hence, in order to compare results obtained in different thicknesses, one should make appropriate corrections by means of a curve showing the variation of the dielectric strength

FIG. 197.

Variation of Dielectric Strength with Thickness of Test Piece. Step-by-step method was employed. BM-021 is a wood-flour-filled phenol resin molding composition. BM-250 and XM-262 are mineral-filled materials. (W. A. Zinzow and T. Hazen.)

*Courtesy Industrial and Engineering Chemistry*

with the thickness, and then all results should be reduced to a standard such as  $\frac{1}{8}$  inch. It is only by this procedure that one can obtain an approximate value for the breakdown of materials having greater thicknesses than can be punctured with the test equipment at hand.

FIG. 198.

Correction Curve for Variation of Dielectric Strength with Thickness of Test Piece. (W. A. Zinzow and T. Hazen.)

*Courtesy Industrial and Engineering Chemistry*

This has been pointed out by Zinzow and Hazen.<sup>5a</sup> Figure 197 illustrates how the dielectric strength of some Bakelite materials varies with the thickness of the sample being tested. A correction curve for use when the pieces are not of standard thickness is shown in Fig. 198.

**Dielectric Strength Parallel to the Laminations.** It has been observed that laminated materials in service frequently break down along the laminations at voltages much lower than one would expect based upon the customary dielectric

<sup>5a</sup> W. A. Zinzow and T. Hazen, *Ind. Eng. Chem.*, 1935, 27, 899.

strength values. Such facts demonstrate that the dielectric strength along the laminations is quite different from that perpendicular to this plane. Hence, it is desirable to test such materials for breakdown along the laminations.

In determining the dielectric strength in this direction the test specimens are cut in squares 2 inches on a side and holes are drilled in opposite edges, at the mid-points, so as to line up perfectly, and to such a depth that the innermost ends of the holes will be exactly 0.5 inch apart. Metal electrodes are fitted snugly into the holes, thus forming a type of needle gap with the material between the ends of the electrodes. It is usually found convenient to make these holes of a diameter equal to one quarter the thickness of the material unless the specimen is extremely thin.

**Arcing Characteristics.** In devising a test for the arcing characteristics of synthetic compositions, it is essential that the procedure used be such as to give information bearing directly upon the particular application in question. If a material is to be subjected to an arc similar to that encountered in automobile ignition outfits, one type of test will differentiate the materials from each other. But if the product is to withstand actual burning under a strong arc, an entirely different method is essential.

For the former type of test, a 15,000 volt transformer is of ample size. The terminals may be placed about  $\frac{3}{4}$  inch apart on the surface of the material to be tested. The arc should be passed between the electrodes at regular intervals about 10 times per minute, each spark having a duration of approximately 0.1 second. This is continued until a carbon path is formed between the terminals. The urea and phthalic glyceride resins are particularly resistant to this form of test.

When dealing with power arcs, the filler is of importance, and it is necessary that it be one such as asbestos which resists actual burning. Numerous devices have been designed to test the power-arcing characteristics of various materials for very specialized applications, such as is the case when the arc is made by a brushing contact and is drawn out over the surface of the product. However, no single test which would give general satisfaction for all possible variations has as yet been proposed.

**Effect of Temperature on Dielectric Strength.** Since laminated material frequently becomes heated when in service, it is essential that something be known of the variation in dielectric strength with temperature changes. In general, a comparison of the strength at room temperature with that determined at 120°C. will be sufficient to predict the behavior of the material under warm working-conditions. If it is desired that the variation be shown by means of a curve, numerous points will have to be taken however. The elevated temperatures can be readily obtained by means of a thermostatically-controlled oil bath, but when making such tests sufficient time should be allowed so that the sample may come to constant heat before making the breakdown determinations. From 15 to 30 minutes will ordinarily be quite ample to establish this condition.

The effect of temperature on the dielectric strength of flat sheets and cylinders has been discussed by Flight.\* The temperature was varied from 30° to 100°C. on papers, mill products, varnished paper, cloth, fiber, wood and some molding compositions. The results showed that the decrease in dielectric strength varied from 15 per cent to 78 per cent at 100°C. as compared with the value obtained at 30°C. Flight suggested that insulating materials be tested at 100°C. and not at room temperature, or, even better, they should be tested at both temperatures.

\* W. S. Flight, *J. Inst. Elec. Engrs. (London)*, 1922, 60, 218; *J.S.C.I.*, 1922, 41, 222A.

Tables and graphs have been compiled by Nuttall<sup>7</sup> giving the relationship between decrease of breakdown and increase of temperature and the thickness of the material. He has determined values for hard rubber and many insulating materials, including Micarta and varnished paper.

**Effect of Frequency on Dielectric Strength.** Montsinger<sup>8</sup> studied the effect of time and frequency on the dielectric strength of various insulating materials and has compiled the relative dielectric strengths with varying frequencies. See Table 70.

TABLE 70.—*Variation of Dielectric Strength with Frequency.*

Frequency	Relative Dielectric Strength of Oil-Treated Pressboard	Relative Dielectric Strength of Solid Insulation
25 cycles.....	1 345	1.25
60 cycles.....	1 000	1.00
200 cycles.....	0.840	0.85
420 cycles.....	0.780	0.73

**Power Factor and Dielectric Constant.** A knowledge of the power factor of materials will aid greatly in classification. By this term, as applied to insulating materials, is meant the ratio of the power loss in a material to the product of the volts across a capacitor and the current in the same capacitor in which the material is used as a dielectric. The dielectric constant of the material is the ratio of the capacitance of a capacitor in which the material is used as a dielectric to the capacitance of the same capacitor with air as the dielectric. Another factor known as the loss factor is also of great help in classifying the various insulatory materials. The loss factor is frequently given as the product of power factor and the dielectric constant.

For flat plates the dielectric constant is readily calculated from the geometrical dimensions of the electrodes used, the thickness of the specimen and the capacitance as determined when making power factor measurements.

$$\text{Dielectric Constant} = K = \frac{(C - C_e)t}{0.0885A}$$

when:

$C$  is the capacitance in micro-microfarads as measured.

$C_e$  is the edge correction.<sup>9a</sup>

$t$  is the thickness of the specimen in cm.

$A$  is the area of each of the two equal electrodes in sq. cm.

0.0885 is a constant.

If the dimensions of the specimen are given in inches the above formula becomes

$$K = \frac{(C - C_e)t}{0.224A}$$

In case the specimen is in the form of a tube, the value of the dielectric constant may be calculated by the equation

$$\text{Dielectric Constant} = K = \frac{3.6t(C_1 - C_2)}{D(l_1 - l_2)}$$

when:

$t$  is the thickness of the tube in cm.

$D$  is the diameter (mean diam.) in cm.

$C_1$  is the measured capacitance of the tube in micro-microfarads for the electrodes of length  $l_1$ .

$C_2$  is the measured capacitance of the tube for electrodes of length  $l_2$ .

<sup>8</sup> V. M. Montsinger, *Electrical World*, 1924, 84, 723; *Chem. Abs.*, 1924, 18, 3660.

<sup>9a</sup> Corrections given in A. S. T. M. *Tentative Standards*, 1932, 827.

The American Society for Testing Materials, through its Committee D-9, has prepared methods for the determination of the power factor for 25-60 cycles or ordinary commercial power frequencies and for frequencies of the order of 1000 and 1,000,000 cycles.

Specimens for power-factor measurements can be prepared by taking pieces about 6 inches square and applying electrodes 4 inches in diameter. These contacts may be tinfoil secured by vaseline, or they may be painted using any suitable conducting paint. The electrodes are placed on each side of the sheet and directly opposite each other. Their size may have to be varied with different thicknesses in order that one will have a reasonable capacitance to measure.

Many factors may be brought to light by power-factor determinations. In practically all materials the presence of water will give a relatively high value at 60 and at 1000 cycles. While the addition of water also increases the losses at high frequencies, the change is much less marked than at low frequencies. After

FIG. 199.

Variation of Power Factor with Temperature. A standard wood-flour-filled phenol resin molding composition was used. (W. A. Zinzow and T. Hazen.)

Courtesy Industrial and Engineering Chemistry

baking, a piece of laminated phenolic stock will greatly improve with respect to power factor at both high and low frequencies. The heating produces further curing of the phenol resins with a resultant lowering of the losses, particularly at high frequencies. The baking also causes a drying action by driving off the water with the result that the losses are greatly decreased at the low frequencies.

Zinzow and Hazen<sup>10</sup> state that, if only one property of an insulator is to be tested, the power factor at low frequencies should be determined since it appears to be the best indicator of insulation qualities. Effect of frequency and temperature on the power factor of molded phenol-aldehyde resins is indicated in Fig. 199. Variation of power factor with moisture content is shown in Fig. 200.

Shearer<sup>9</sup> has shown that laminated phenolic materials have very little if any difference in their dielectric constant and power factor at 150 and 1500 kilocycles. This change in frequency is in the range where the variation to be expected in dielectric constant is relatively small. Tests at 60 cycles and 1000 kilocycles do show considerable differences depending upon the materials.

Dellinger and Preston<sup>10</sup> found some samples to exhibit changes in power factor with time and the season of the year. Following these observations, Preston and Hall<sup>11</sup> made a study of several representative samples, during 1920 and

<sup>10</sup> W. A. Zinzow and T. Hazen, *Ind. Eng. Chem.*, 1935, 27, 899.

1921. From observations on about a dozen taken during the course of the year they drew the following conclusions: The power factor of the samples tested varied with the season of the year, reaching a maximum in late summer, usually lagging behind the seasonal variation of atmospheric humidity and temperature. In general, the power factor returned to its original value after undergoing a year's cyclic changes. A few of the samples showed a slight increase at the end of the year. The variation of power factor between two samples of the first grade of materials of the same make and color was greater than the amount of season variation. The seasonal variation for the second-grade materials was more than the difference between two samples of the material.

**Electrical Resistivity.** Inasmuch as both temperature and humidity have a most decided effect on the resistivity of laminated or molded material, it is highly desirable that the method of test adopted for the purpose can be applied under

FIG. 200.

Variation of Power Factor of Molded Articles with Moisture Content of Molding Powder. Frequency 1000 Cycles (W. A. Zinzow and T. Hazen.)

special conditions. It is for this reason that the following procedure is suggested as more satisfactory than that proposed by the American Society\* for Testing Materials.<sup>12</sup>

The form of the specimen should be a rectangular strip 7½ inches long and 2½ inches wide. Spaced along the center line of the piece, at intervals of 1¼ inches, are bolts, ⅛ inch in diameter, fitted with washers ½ inch in diameter. Using the washers as terminals, it will be found convenient to measure the resistance of the intervening material under extreme conditions of moisture and temperature.

Exposure to humid conditions will cause a marked decrease in the resistance of most laminated materials. Exposure to elevated temperatures alone will cause the volume resistance to decrease enormously. Hence, determinations of this kind are extremely important in evaluating the relative qualities of different products. A material which has its surface resistance greatly affected by exposure to humid conditions or heat is certainly not as well suited for use where moisture or high temperatures may be encountered as one that is but slightly altered in the same length of time.

Owen and Thomas<sup>13</sup> have given a review of the available data on the application of synthetic resins to electrical insulating purposes. The materials were considered from the standpoint of their electrical and mechanical characteristics and

<sup>12</sup> A. S. T. M. Standards (D257-33), 1933, II, 1107.

<sup>13</sup> W. D. Owen and A. M. Thomas, *J. Oil, Colour Chem. Assoc.*, 1931, 14, 290; *Chem. Abs.*, 1932, 26, 609.

also in the light of their chemical structure. A special point brought out in the discussion was the fact that phenol-aldehyde materials manufactured with an alkaline catalyst differ considerably from those made in the presence of an acid catalyst.

**Hardness.** In general, determinations of hardness of laminated materials are not made by the same methods which are applied to metals. Certain of these tests have been of value in some cases, however, and the following methods have yielded good results.

(a) *Brinell Hardness.* This test consists in the determination of the amount of the indentation produced in the material by a load of 500 kg. applied to a ball 1 cm. in diameter placed on the surface of the material. The hardness is calculated as follows:

$$\text{Hardness} = H = \frac{P}{2\pi rd}$$

when:

$P$  is the force applied = 500 kg.

$r$  is the radius of the ball in millimeters = 50 mm.

$d$  is the depth of the indentation produced by the load on the ball and is read from a gage on the apparatus.

(b) *Scratch Hardness by Agate Point.* It is frequently of interest to have some measure of the relative ease with which various surfaces become marred or scratched during service. As yet no method has been adopted as standard; but a procedure, known as the agate-point scratch test, has been used quite satisfactorily as a means of distinguishing between the relative liability to scratching of various surfaced materials. A ground agate point in the form of a 90° cone is mounted in the end of a rod held perpendicular to the surface so that it may be drawn in this vertical position across the face of the sample. A collar is fastened on the rod bearing the agate point and various masses are added above this collar as desired. The weight is increased until the total mass bearing on the agate point is just sufficient to make the first visible scratch on the surface of the material. The scratch hardness is then stated as the total load required to produce this first marring. Such an apparatus is extremely simple but can be used quite advantageously in obtaining comparative results. A more elaborate piece of apparatus based upon this principle is so arranged that, as the scratching point is drawn over the surface in question, the total mass pressing down on the surface is gradually increased. The point at which the scratching point makes the first visible indentation on the surface is noted, and from this position the mass pressing on the point can be determined from the constants of the machine.<sup>14</sup>

**Coefficient of Friction.** Instances occur in which it is of interest to know something of the sliding resistance encountered when drawing a laminated product over the surface of some other material, but it is seldom that the static or rolling friction is of real importance. Consideration here shall be confined to the resistance offered when one material is moved over another surface, either of the same or different material.

A simple method of conducting the test consists of setting up a disc which can be rotated in such a manner that the material under test may be held against this revolving surface with various pressures. An arm concentric with the rotating disc may be employed to hold specimens at various distances from the axis of rotation and various masses can be applied to a weight holder. Such an arrangement permits the investigation of the effect of various surfaces, speeds and unit

<sup>14</sup> Certain of the hardness tests described in Chapter 70 for use with varnishes may also be employed.

pressures. The amount of the friction force is determined by pressing the end of the lever arm upon a suitable scale.

**Special Tests in Gear Stock.** In addition to the Charpy impact test, manufacturers of canvas-base materials have used other procedures to classify their products for use in gears. Of these, the following methods are typical.

(a) *Tooth Strength Test.* The simplest procedure for the determination of the endurance of gears is to allow a considerable mass to fall through a definite height, say 1 inch, so as to repeatedly strike one of the gear teeth on the pitch line. The weight is raised at regular intervals by means of a cam and lever arrangement and allowed to fall repeatedly until the tooth fails. The test can be repeated upon as many teeth as desired, so long as it is possible to hold the gear rigidly. In one arrangement every fourth tooth is destroyed. This test has a disadvantage in that it is necessary to prepare a finished gear and then test it to destruction without securing a real measure of its probable life in service.

(b) *Hammer Test on Gear Stock.* A method that has been found useful by some manufacturers of gear stock is made with the same apparatus as outlined above. However, instead of a finished gear a test section  $\frac{1}{4}$  inch by  $\frac{1}{4}$  inch by 1 inch cut from the gear stock is used. A mass of 25 lbs. is allowed to fall repeatedly from a 1-inch height so as to strike the test piece endwise until the piece is crushed. The specimen is cut in such a manner that it will be struck on the edge of the laminations.

(c) *Life Test on Gears.* The most satisfactory measure of the merits of a gear material is obtained by making life tests on products made from the material. The gear under test is used as an idler between a motor and a generator so that it can be subjected to various increasing loads and, in this way, run to destruction. While service under normal load gives the only true measure of the quality of a gear stock, it is not feasible to carry out all testing in this manner as it would require, under ordinary conditions, a prohibitive amount of time. The test can be accelerated by varying the load at stated intervals until the gear is destroyed as, for example, with the following routine which has been found to give a satisfactory index of endurance. A gear, which has been measured for thickness with a micrometer and similarly has been checked with a tooth comparator, is run at normal load for a period of 24 hours. The measurements are taken again subsequent to the initial run and the load is then increased to twice the normal figure, after which the gear is driven for a similar period. This process of increasing the driving force by increments equal to the normal load after each 24-hour run is continued until the gear fails. Employing a gear  $\frac{1}{2}$  inch thick, having forty-four  $14\frac{1}{2}^\circ$  spur teeth and a diameter of  $5\frac{1}{2}$  inches, it has been found that some materials fail under normal load, and some have lasted until the end of a 24-hour period at 4 times the rated or normal load. A tooth of the above-described gear will have a thickness at the pitch line of about 0.195 inch when new, but generally failure does not occur until the tooth has worn down to a thickness of 0.180-0.185 inch. For the poorer grades of material, however, the gears fail before the thickness of the teeth has been reduced to such a degree.

**Bonding Strength.** The extent to which the composite layers of a laminated product are bonded together is always of importance in classifying the type of material. This test is made on a specimen 1 inch square of the same thickness as the original sheet. Care should be taken in cutting so that the edges will be true and smooth. The piece is placed on edge and loads are applied to a steel ball, 1 cm. in diameter, which should be centered accurately between the two edges and the ends of the specimen. The load is increased until the sample splits. This

test is not readily applied to pieces which have a thickness less than  $\frac{1}{4}$  inch unless great care is taken, since the ball is likely to break out on one side, giving misleading results.

Another method which has been found to be quite satisfactory for a study of bonding strength, is to make use of the test specimen illustrated. (See Fig. 201.) The material to be tested can be cut into strips 1 inch wide and a hole,  $\frac{1}{8}$  inch in diameter, is then drilled parallel to the laminations at the exact mid-section. The sample is machined along the diameter of the hole and cut off so as to be exactly  $1\frac{1}{16}$  inch in length by 1 inch high when the piece is held with the groove on the top face. A drill rod  $\frac{1}{8}$  inch in diameter is placed in this channel and

FIG. 201.—Specimen for the Determination of Bond Strength in Laminated Material.

pressure is applied on the drill rod until failure occurs. In testing materials less than  $\frac{1}{4}$  inch thick it is best to hold the specimen in a clamp that grips half-way up the piece so as to hold it firmly in a vertical position. If the sheet from which the samples are to be cut is extremely thin, a groove  $\frac{3}{64}$  inch in diameter may be used if the test piece is  $\frac{1}{2}$  inch square. Under these conditions a jig must of course be used to maintain rigidity.

**Cold Flow.** When laminated materials are so used in service that they are subjected to sustained pressures such as arise from tightening up bolts, distortion frequently occurs. This may be the result of either one or a combination of two causes; shrinkage may have taken place because of drying or else the material has distorted under the influence of a load which is greater than the elastic limit. Synthetic resin materials do not appear to have a sharply defined elastic limit as is true of steel and certain other metals since a load, small in proportion

to the maximum allowable fiber stress, will cause a permanent deformation which is not in accord with Hooke's law.

The specimen used in determining the cold flow of a laminated material is preferably a cube,  $\frac{1}{2}$  inch on a side, or, in the case of thin products,  $\frac{1}{2}$  inch squares piled up to give this form. The sample is subjected to a pressure of 1250 pounds, and the variation in height during the continued application of the load is determined by means of a micrometer gage at intervals over a period of 24 hours.

The Rockwell hardness machine may be adapted to determine the cold flow of these materials. A 100 kg. load is applied to a  $\frac{1}{8}$  inch diameter ball placed on the surface of the material. Measurements are made of the change in the depth of the indentation while the load is applied; and, if desired, these observations may be extended over several hours. It should be remembered that such tests are not well adapted to thin materials where the influence of the ball may extend through the specimen.

**Thermal Conductivity.** Determination of thermal conductivity of sheet materials is best made by the method which has been developed by the American Society for Testing Materials.<sup>16</sup> A sheet of material of known thermal characteristics is placed in series with the sheet of the material to be tested between surfaces one of which is at a higher temperature than the other. After equilibrium has been established in the flow of heat from the hot to the cold surface through the two materials, the drops in temperature through both the standard and the sample under test are determined by means of thermocouples placed at the mid-points of the sides of each specimen. A convenient size for the heating and cooling plates is 8 inches square if the samples are not over  $\frac{1}{2}$  inch thick.

The absolute thermal conductivity of a material requires a somewhat more elaborate procedure. Two specimens of the material to be tested are placed one on each side of a surface in which the heat is distributed uniformly. Such a source of heat is composed of two parts, a central heating surface of definite dimensions and a surrounding guard-ring heater so arranged that the temperature can be separately controlled. In the measurements, however, it is only necessary to determine the heat developed in the central heater. On the opposite sides of the specimen are two cooling surfaces, maintained at constant temperature by water-cooling. Thus the heat developed in the central heater flows laterally through the samples at right angles to the hot surfaces, and is absorbed by the cooling plates. The temperature drop in the specimen is measured by means of thermocouples.

**Distortion Under Heat.** When sheet material is placed in service it is subjected to variations both in fiber stress and in temperature. Since an increase in temperature decreases the allowable fiber stress, the relationships between distortion, unit stress, and temperature become of importance.

The following method<sup>16</sup> has been developed for use with molding materials, but it is equally applicable to laminated products. A test specimen 5 inches by  $\frac{1}{2}$  inch by  $\frac{1}{2}$  inch is placed on supports 4 inches apart and subjected to a load of 2.5 kg. at its mid-point. (See Fig. 202.) The temperature is raised at the rate of 1°C. every 2 minutes until the deflection at the center of the beam reaches 0.010 inch. The temperature at which this occurs is called the heat-distortion point for the material. While the method specifies the exact size of the specimen and the resultant distortion, these can be varied to suit individual requirements.

If the specimens are taken from sheets less than  $\frac{1}{2}$  inch thick the same pro-

<sup>16</sup> A.S.T.M. Tentative Standards (D352-51T), 1933, 795.

<sup>16</sup> A.S.T.M. Standards (D48-53), 1933, II, 1101.

cedure may be applied, provided the force used is reduced so that the same unit stress, 265 lbs. per square inch, is maintained in the test sample. If it is necessary to reduce the distance between supports, the critical distortion should be proportionately diminished.

**Deterioration Under Heat.** Indications of failure of laminated or molded products due to exposure to heat may be found within a reasonably short time if the material can be subjected to heating conditions which are more severe than those found in service.

FIG. 202.—Apparatus for Temperature Tests.

The question generally arises as to what properties of the material will most readily show the ill effects of continued heating, since, in general, certain of the electrical coefficients tend to improve. However, it will be found that any of the mechanical properties are impaired by exposure to high temperatures. A specimen prepared for either impact, tension, crushing or transverse testing will fail at a lower point after subjection to heat for a considerable time. Accordingly, the procedure selected should be that which will measure the type of stress most likely to be encountered.

Having decided on the particular test, and therefore on the type of specimen, a large number of samples, usually about 100, are prepared and placed in an oven at approximately 150°C. Five or ten of the specimens should be tested prior to heating so as to obtain the values of the material before treatment is commenced. It is also necessary to previously determine whether or not the samples can be placed in an oven at such a temperature without causing them to blister.

To avoid this the samples can be exposed to a temperature of about 100-110°C., gradually raised to 150°C. during the course of 8-24 hours. The continuous heat treatment is then begun and tests may be made on groups of 5 specimens at intervals of 24 hours, 96 hours, 8 days, 16 days, and monthly thereafter. The specimens are first cooled to room temperature, upon removal from the oven, in a desiccator. They are then conditioned for 24 hours at 60 per cent relative humidity and 30°C. and finally tested under room conditions immediately after the conditioning. Such a series of tests will classify the materials as to their ability to withstand continuous service at elevated temperatures.

**Gloss.** The gloss or luster of a surface is usually reported as the reflecting power of the material. There are several instruments and methods that have been used for such determinations. These are, however, all designed for special applications. In the case of the Pfund glossmeter the material to be tested is rotated in such a way that light, falling upon this revolving surface, is reflected through a tube having a photometer at its end. Measurements are compared with the reflection from a glass surface as a standard and the results are given in relative terms. The Ries-Gilbert glossmeter employs a lamp as a source of light which, after reflection from the test surface, is measured by a photometer. The instrument can be so arranged as to indicate directly the light produced by the source. The values include not only the specular but the diffuse reflected light. Schulz<sup>17</sup> has compared the normal and diffuse reflection of light from a standard source by means of an instrument known as the Goerz "Glanzmesser." Polarization luster-measuring devices are somewhat inconvenient, however, as they require adjustment to the refractive index of the substance under examination.

## PART II

### TESTING OF MOLDING AND MOLDED MATERIALS

Certain of the test procedures<sup>18</sup> described in the preceding portion of this chapter may be applied to molded articles as well as to laminated materials. However, there is a group of examinations<sup>19</sup> developed for properties peculiar to molding compositions, and it is with these tests that this section will deal.

**Bulk Factor.** It is essential to know the bulk factor of a material if the molds in which it will be used are to be correctly designed. This characteristic is the ratio by volume of the loose molding powder to the resultant finished article. Knowing the maximum bulk factor of all materials to be used in a specific mold, the designer is able to calculate the cavity he must allow to hold a sufficient amount of powder. The usual method of determining this factor is to allow the molding powder to flow freely into a vessel of known volume. Then a piece, say a 2-inch disc, is molded, using the measured quantity of powder, and the volume of the molded piece is determined from its dimensions. The bulk factor may then be calculated from its definition.

Two other ratios are of importance in connection with molding powders. One of these is the ratio of the volume of the loose powder or molding composition to the resultant "pill" or preform when compressed in the customary way. The second ratio is that of the volume of the preform to that of the resultant molded piece. By preforming<sup>20</sup> the material, it is possible to use a mold having coincid-

<sup>17</sup> H. Schulz, *Textilber*, 1924, 5, 25; *Chem. Abs.*, 1924, 18, 934.

<sup>18</sup> The following tests, detailed for laminated materials, may be applied directly to molded articles without adaptation: Flexural strength, impact strength, water absorption, dielectric strength, arcing characteristics, power factor, dielectric constant, electrical resistivity, hardness, coefficient of friction, cold flow, thermal conductivity, deterioration due to heat, heat distortion, and gloss.

<sup>19</sup> A.S.T.M. Standards (D48-33), 1933, II, 1097.

<sup>20</sup> Reference should be made to Chapter 67 for a further discussion of preforming.

erable less volume than could be done were the powder used in the loose condition. In addition, this preliminary compression allows a better flow of the material during the molding operation. The possibility of entrapping gas within the finished article is minimized when using preforms.

**Density or Specific Gravity.** In the use of molding materials there are two densities that are of interest to manufacturers of finished articles. One of these is the specific gravity of the molded product and is of importance in determining the actual weight or mass of a finished piece. The other quantity is known as the density of the powder. It is necessary to know this value as well as the bulk factor in order to figure the cost of the material used in making a given product. This is due to the fact that the material is purchased by weight and that the quantity of material used by volume is determined from the bulk factor.

The density or specific gravity of the finished molded article can be determined by the usual method of weighing the piece in the air and again when suspended in liquid. For most molded materials water may be used, as absorption during the weighing operation is negligible.

The density of the molding powder may be obtained from the weight of a given volume of the powder. The material should be allowed to flow from a hopper into a container of known mass and capacity which may be subsequently weighed.

**Screen Analysis.** An analysis of the various screen sizes of the constituents of molding materials may be of considerable interest to both the manufacturer and consumer of molding materials. The consumer is particularly interested in a material of certain particle size such as will have definite characteristics during the molding operations. If the powder at one time has a high percentage of very coarse particles and a relatively small amount of fines, and later the distribution is reversed, considerable adjustment may be required to produce a satisfactory finished piece. A study of the size and distribution may be made by choosing a series of screens such as 8, 12, 16, 20, 34, 40, 50, 70, 100, and 140 mesh.<sup>21</sup> A weighed amount of the material is placed in the coarsest sieve at the top of the set when stacked as listed, and the whole assembly is agitated. The amount of material left on each screen will give an accurate estimation of the particle size and distribution when expressed as a percentage of the total mass employed.

**Tests for Molding Characteristics.** In connection with the development and use of new molding materials, it is necessary to make some tests to determine the manner in which the composition may be expected to mold under the conditions planned and also to determine what variations from standard procedures are desirable in order to give the most satisfactory product.

(a) *Cup-Closing-Time.* The cup-closing-time is probably the most widely used method designed to study the characteristics of a new material. Generally, the mold used will form a cup about  $2\frac{1}{2}$  inches high, having a diameter of 2 inches at the top and  $1\frac{3}{4}$  inches at the bottom, with a wall thickness of approximately 0.100 inch. The charge is placed in the mold, which should be at the temperature ordinarily used for that type of material. Pressure is applied and the time noted that is necessary for the composition to fuse, allowing the mold to completely close. If the cup fills out and has a good appearance, the test is considered satisfactory. If the piece is poorly formed or has a poor surface the tests will have to be repeated under various conditions of quantity of material, tem-

<sup>21</sup> These sizes have openings of 2380, 1630, 1190, 840, 590, 420, 297, 210, 149, and 105 microns respectively.

perature and pressure until a satisfactory cup is produced or it is shown that the material itself is at fault.

(b) *Disc Mold.* A test which has been of service consists of molding a thin disc, say  $\frac{1}{8}$  inch thick, and 4 or 5 inches in diameter. A material which will not flow to form a large-diameter disc from a small heap of powder will, in general, not prove to be useful for general commercial molding.

Another method which has been used to study the flowing characteristics of a molding preparation is to force the material through a measured orifice while in the fused state.<sup>23</sup> Several variations of this procedure have been found to be of value. In general, the methods are all similar in that they fuse the specimen powder in a cylindrical mold and then force it through an orifice of about  $\frac{1}{16}$  inch diameter. The time elapsing until the material ceases to flow through the opening has been suggested as an indication of the flowing characteristics. It is also possible to weigh the amount forced through the orifice and thus calculate the percentage of the total mass which was extruded.

The most intensive studies of plastic flow have all been based upon the ability of the material to pass through a small uniform or tapered opening. One such method has been described by Peakes<sup>24</sup> while Dillon and Johnston<sup>25</sup> have compiled data on the extrusion of rubber. They include in their article the theoretical and mathematical discussions of this and other test methods. Manfred and Obrist<sup>26</sup> have suggested that the plasticity of the molding composition bears a direct relationship to the physical characteristics such as modulus of elasticity and tensile strength of the finished product. Forrer<sup>27</sup> has reviewed the entire subject of the determination of the plasticity of molding compositions including the procedures for such examinations.

(c) *Setting-Time.* The setting-time of a material can be measured by the use of a cup mold, disc mold or by forcing the composition through a small orifice as described above. The setting-time must be considered for two different methods of treatment, however, since in some cases the material is cooled in the mold, while with other compositions it is removed hot. In either case this period is taken as the best interval in which one can obtain a satisfactorily molded piece.

**Tensile Strength.** The need of a standard tensile strength test was early realized by the American Society for Testing Materials, and their studies, extending over a number of years, have brought this phase of the examination of molding materials to a very satisfactory state.<sup>28</sup> Instead of the original specimen used for many years in connection with molding compositions and cement, a test shape has been developed which is so designed that the breaking strength is unaffected by the stresses due to the jaws holding the sample. (See Fig. 203.)

**Impact Strength.** A large proportion of the trouble caused by the breakage of molded materials in service can be attributed to their low impact strength. The most convenient tests on molded materials for their resistance to shock involves the use of the Izod (cantilever beam) or the Charpy (simple beam) machines.<sup>29</sup> This procedure is similar to that given for the testing of laminated materials, a notched specimen being used in both cases. Satisfactory results may be obtained with an unnotched sample, however, if care is taken, in fact impact tests have been made on pieces cut from finished articles.

Preferably, however, the specimens are  $\frac{1}{2}$  inch square in cross-section for both

tests. The notch may be either milled or molded, but in any case should be cut at  $45^\circ$ , have a depth of 0.10 inch with its point rounded to a radius of 0.010 inch.

FIG. 203.—Tension Test Specimen and Holder for Molded Materials.

Although unnotched specimens may be used, it is desirable to check results given for such tests with those obtained with a notched sample from time to time since the discrepancy due to the lack of the notch varies with different materials.

In making the tests, the material should always be broken in the direction in which pressure was applied during the molding operation. Before making a test the specimens should be conditioned by placing them in an oven for 48 hours at a temperature of  $122 \pm 2^\circ\text{C}$ . The pieces may then be removed from the oven and cooled in a desiccator at room temperature before being tested.

**Compression Strength.** The standard specimen for compression testing of molding compounds is a cylinder  $1\frac{1}{8}$  inches in diameter and  $1\frac{1}{4}$  inches long.<sup>29</sup> The piece is molded in the direction of the axis of the cylinder. For control tests giving comparative results it may be quite satisfactory to make tests on other shaped specimens, however. Cubes,  $\frac{1}{2}$  inch on a side, have been used with very uniform results. Such shapes are well suited to determinations of the crushing strength in directions other than that in which the molding pressure was applied. It is of importance to exactly define the type of specimen employed in reporting the results of compression tests, as exact agreement can not be expected between samples of different shapes.

**Dielectric Strength of Molded Materials.** The general procedure is the same as that given under the corresponding test for laminated materials. The specimens used are discs of 4 inch diameter,  $\frac{1}{8}$  inch thick for hot-molded materials, and  $\frac{1}{4}$  inch thick if worked cold. The electrodes are also circular in form with a diameter of 1 inch. The test should be conducted under oil to avoid possible flashing over the surface. The procedure<sup>30</sup> may be either the short-time, step-by-step, or endurance variation as previously described, the sole difference being that in the short-time test the potential should be raised at the rate of 1000 instead of 500 volts per second.

## Chapter 70

# Testing of Synthetic Resin Coatings

In this chapter, the tests for synthetic coatings will be described in general terms, the object of the examination will be pointed out, wherever possible interpretations of the results will be given and references will be cited for the exact procedures. General tests are given first, covering the methods used in determining physical properties, curing characteristics and aging tests, followed by the more specialized methods.

### SPECIFIC GRAVITY

In determining the specific gravity of a varnish, use may be made of a pycnometer, a Westphal balance or a hydrometer so graduated that the values can be determined within a tenth of a per cent. It is quite essential that the temperature of the varnish be kept constant and determinations should be made at  $20 \pm 0.5^\circ\text{C}$ . For most work the results should be reduced to a temperature of  $20^\circ\text{C}$ . In general it will suffice to apply a correction of 0.0007 per  $1^\circ\text{C}$ . to be subtracted from the observed value for temperatures below  $20^\circ\text{C}$ . and added for those above that point.

### VISCOSITY

Viscosity may be determined either relatively or absolutely. For relative determinations use can be made of a set of viscosity tubes such as are quite generally employed in the varnish industry for comparison and control work. The temperature of the varnish should be maintained within  $0.5^\circ\text{C}$ . while observations are being made. For such work a graduated pipette which is capable of giving reasonably accurate values would be permissible, but even with these indirect methods, the instrument should be calibrated for satisfactory results. Oils of known viscosity for determining the constants of such apparatus can be obtained from the U. S. Bureau of Standards.

If the above instruments are standardized, it is possible, by the use of correction factors, to express the coefficients in absolute units, that is, poises or centipoises.<sup>1</sup> For the measurement of viscosity reference should be made to the A. S. T. M. methods.<sup>2</sup> Some instruments, such as the MacMichael viscosimeter, are calibrated by the manufacturer so that the viscosity can be read directly in poises or centipoises. The Höppler viscosimeter, which was demonstrated before the World Petroleum Conference in London, 1933, also has many advantages. This instrument consists of a precise-diameter glass tube set at an angle of  $70^\circ$  to

<sup>1</sup> The absolute viscosity in c.g.s. poises has been defined as the force in dynes required to move, at a velocity of one centimeter per second, a square centimeter surface past another parallel like surface one centimeter away, overcoming the resistance to shear of the intervening liquid. The absolute viscosity for water at  $20^\circ\text{C}$ . is approximately 1.0 centipoise.

<sup>2</sup> A.S.T.M., *Tentative Standards (D115-31T)*, 1931.

the horizontal, surrounded by a water jacket so that the temperature may be controlled within narrow limits. Supplied with this tube are gold-plated steel balls which are somewhat smaller than the internal diameter of the tube. The diameters of these balls are graduated, and the proper selection depends upon the viscosity of the liquid to be treated. Since the ball is almost the same diameter as the tube, the flow of the liquid in the annular space between the tube and ball is laminar, preventing disturbances due to turbulence. The ball selected for the determination is the one which will require at least 6 times as many seconds to fall through a prescribed distance on the tube as this distance is in centimeters. The apparatus has the peculiar advantage of being adaptable to determinations on gases, liquids or materials of viscosities as high as 1,000,000 centipoises. It can even be used with substances that are not transparent as one can note the position of the ball when it touches the glass on the rear of the fall tube.

#### FLASH POINT

The flash point of a varnish is that temperature at which the vapor above the liquid ignites upon the introduction of a flame. In determining this characteristic, a definite quantity of the specimen is placed in a specially designed closed vessel, and the temperature of the varnish is gradually raised at a specified rate by heating the surrounding bath. This procedure has been standardized by the A. S. T. M.<sup>a</sup>

#### TIME OF CURING

The determination of the time of curing is especially valuable in the case of varnishes used to impregnate cloth or paper. These materials are cured in a press under the influence of heat and pressure, thus forming a finished laminated board. The time required to cure a varnish resin is of importance since the entire processing of phenol resin and urea resin laminated materials depends upon this quality. The time of curing is defined as the time which is required to transform the resin contained in the impregnated cloth from the soluble fusible state to the infusible form. Such treatment changes the loose pile of sheets of impregnated material into a compact, rigid mass. The stiffness of a molded plate depends upon the thickness of the product, the type of varnish employed and the percentage of varnish and filler.

As a measure of the time of cure of phenolic resins, use can be made of the determination of a state of the varnish or resin known as the "End Point." After heating for a certain length of time, at a predetermined temperature, it will be found that the varnish no longer flows from the stirring rod but instead clings, exhibiting much the behavior of a piece of over-stretched rubber. When this occurs the end point has been reached. The period during which the varnish has to be heated under the definite conditions of temperature in order to reach this state is known as the "Set Time." A convenient method of making this determination is as follows: Ten cubic centimeters of the varnish are placed in a vessel having a bottom area of 20 square centimeters and a height of 8 to 10 centimeters. This container is placed in a steam jacket so that it may be kept at a temperature of 135°C. The varnish is stirred during heating and the interval required to reach the end point is taken as the set time.

The vessel used in this test should have a cover with an opening not larger

<sup>a</sup> A.S.T.M. Standards (D66-31), 1933, II, 805.

than twice the diameter of the stirring rod. It should be borne in mind that in making comparisons of different varnishes or even of the same varnish having different solvents, values may vary because of the difference in time required to evaporate the vehicle, since this must be done before the varnish starts to cure appreciably.

#### PERCENTAGE OF NON-VOLATILE MATTER

Since the essential action of a given varnish depends upon the non-volatile constituents, it is of considerable interest to the consumer to know the proportion of solvent and base in the product.

The non-volatile matter by weight may be determined in the following manner: A small sample of the material is placed in a beaker approximately eight centimeters in diameter and carefully weighed. The container and varnish are then heated for three hours in an oven at  $110 \pm 1^\circ\text{C}$ . The dish and residue are then cooled, preferably in a desiccator, and accurately weighed. Knowing the weight of the beaker and resin, and of the dish alone, the weight of the residue can be found. The ratio of the residue to the original sample by weight represents the percentage of the non-volatile matter. For comparative work it is essential that the same weight of varnish be taken each time and that identical receptacles be used in all determinations.

Users of phenolic type of varnish who impregnate cloth or paper and then press it into boards, or other shapes, are interested in knowing the volatile content of the impregnated material before it is pressed. To make this determination a piece of cloth or paper is cut from the sheet after it has been impregnated and passed through the drying tower but before it passes around the final roll. This piece is accurately weighed, heated for 10 minutes at  $160^\circ\text{C}$ . and reweighed. In both cases sufficient time is allowed for the sample to cool to room temperature, preferably in a desiccator. From the masses determined by the two weighings the percentage of volatile matter given off is known. Then from the average mass of a sheet of the unimpregnated paper or cloth of the same size as the sample tested, the non-volatile matter by weight can be obtained. Unfortunately, no standards have been adopted as to the temperature at which the sample should be heated nor as to the exact length of time of treatment. It therefore falls upon the consumer to ascertain for himself the most suitable limits of time and temperature for his purposes. Eventually, the exact procedure will be definitely established, but it may be that different temperatures and times of heating will be found necessary for different classes of materials. In making this test care must be taken to see that the resin is not polymerized, that the solvent is driven off and that the moisture content of the paper or cloth is not materially changed. Lower temperatures may be used when the resin is easily polymerized.

It is sometimes of interest to determine the volume percentage of solvent in a varnish and thus arrive at the composition of the varnish with respect to solvent and base constituents. This information may be secured by distilling 100 cc. of the varnish.<sup>4</sup> For phenolic varnishes the distillation should be carried on until the volatile distillate comes over slowly, or until the residue begins to gel. Care must be exercised not to raise the temperature too high and thus carry the process too far.

The specific gravity of the volatile matter recovered by the distillation may then be found by one of the usual methods. Likewise the specific gravity of the

<sup>4</sup> Method of Test for Distillation of Gasoline, Naphtha, Kerosene and Similar Products, *A.S.T.M. Standards*, (D88-50), 1933, II, 778.

original varnish should be determined. The percentage of the volatile matter by volume is then given by the formula

$$X = \frac{AC}{B}$$

X—the percentage of volatile matter by volume.

A—the specific gravity of the original varnish.

B—the specific gravity of the volatile matter recovered by the distillation.

C—the percentage of volatile matter by weight as determined above.

#### TIME OF DRYING

The procedure for this test as adopted by the American Society for Testing Materials<sup>5</sup> specifies the use of pieces of brass or copper, about 4 centimeters wide and 20 centimeters long, thoroughly cleaned and polished. The strip is dipped into the varnish at room temperature and is withdrawn uniformly at the rate of 38 centimeters per minute. The consistency of the varnish should be such that when dry the thickness of the film on each side of the metal strip will be between 0.022 and 0.026 mm. For air-drying varnishes, the film is dried in a dust-free atmosphere at 20°C. In the case of baking varnishes, the specimens are dipped and allowed to drain at room temperature until the varnish is set. The coating may be said to have set when a finger print made by lightly pressing at a point two inches from the bottom of the panel will not become obliterated by further flow. It is then dried in an oven at 110±1°C. The specimens are taken from the oven at intervals and tested for dryness. A suggested time for the removal of the first sample is thirty minutes. The others may be tested at intervals of 10 minutes. The varnish is considered to be dry when a piece of kraft paper 38 mm. wide, 152 mm. long and approximately 0.063 mm. thick does not adhere when pressed against the coating for one minute by a cylindrical one-pound mass one inch in diameter. The paper is applied near the center of the specimen and at right angles to the length. This is done at room temperature after the specimen has cooled. In the case of varnishes which dry "tacky," the time of heating must be continued until the resistance to removal of the paper appears to have become constant.

Wolff<sup>6</sup> has pointed out that in determining drying time of varnishes it is necessary to use care that exactly similar conditions are obtained. This is especially true in the case of relative humidity. He points out that a given finish which required 10 hours to dry in air at 40 per cent relative humidity needed 13 hours at 70 per cent and only dried after 20 hours at saturation. Another, however, required 11 hours at 40 per cent humidity, 12 hours at 70 per cent and 14 hours in saturated air, so that it is impossible to establish any relationship between drying time and humidity. Wolff applied a piece of clean paper to the film after definite intervals of time and obtained his values by measuring the force required for separation.

A simple device for determining the drying time of paints and varnishes<sup>7</sup> employs glass or rubber tips placed at the end of a balance arm. These are impressed upon the coating with a definite load. When the glass tip does not pick up the film, the material is set, and when the rubber tip does not mar the surface, as the specimen is drawn along under it, the film is considered dry.

<sup>7</sup> F. N. Stearns, *Circ., Am. Paint, Varnish Mfrs. Assoc.*, 1932, 423; *Chem. Abs.*, 1932, 27, 614.

Sanderson<sup>\*</sup> has also described a satisfactory way of determining this value. A disc, carrying a specimen film, is placed on a slowly rotating vertical shaft. As the coating is revolved, sand flows upon it in a small stream describing a spiral, since the point at which the particles strike the film gradually moves towards the center of the plate. The varnish has dried dust-free when the sand no longer adheres to the surface. Knowing the speed of rotation of the disc, usually one revolution every three hours, the length of the spiral measures the period elapsed.

FIG. 204.—Drying-Time Meter. Also shown are instruments for recording humidity, temperature and atmospheric pressure.

Gardner<sup>\*</sup> has made suggestions regarding the utility of certain grades of synthetic resins for the manufacturing of quick-drying varnishes, and he gives the results obtained through the use of these materials in the production of various grades of coatings.

#### HEAT ENDURANCE

To test the resistance of a finish to heat, a thoroughly cleaned sheet of copper or brass 20 cm. by 3 cm. by 0.127 mm. thick is used.<sup>10</sup> The specimen to be examined should be of such consistency that the dry film will have a thickness between 0.022 mm. and 0.026 mm. In preparing the film the metal strip is dipped twice into the varnish in opposite directions and withdrawn at the rate of 38 centimeters per minute. The varnish at the time of applying the coating should be at a temperature of about 20°C. and the time between the first and second coats must be long enough so that the first coat is properly dried. After the second coat is hard, as determined by the drying time test, the specimens are heated in an oven at a temperature of  $110 \pm 1^\circ\text{C}$ . At the end of each 24-hour period a specimen is removed and bent around a rod an eighth of an inch in diameter. The heat endurance of the varnish is taken as the number of hours of heating in a well-ventilated oven at  $110^\circ\text{C}$ . at which the film shows the first signs of cracking upon distortion.

#### OIL RESISTANCE

To determine the ability of a varnish to withstand the action of oil, a specimen film is prepared in the same manner as for the preceding test. The samples are

<sup>\*</sup> J. M. Sanderson, *Proc. Am. Soc. Testing Materials*, 1926, 26 (3), 556; *Chem. Abs.*, 1927, 21, 1363.

<sup>\*</sup> H. A. Gardner, *Circ. Am. Paint, Varnish Mfrs. Assoc.*, 1926, 279; *Chem. Abs.*, 1926, 20, 3354.

<sup>10</sup> A.S.T.M. *Tentative Standards (D115-31T)*, 1934.

then dipped into a typical transformer oil at a temperature of  $110 \pm 1^\circ\text{C}$ . for 48 hours. The panels are duly removed from the oil and the effect of the hot oil on the varnish film examined. Sometimes the disintegration of the varnish film can be detected from the turbidity of the oil. This can be observed by holding two samples of the oil, one filtered and the other unfiltered, before a diffused light. Again if the disintegration is pronounced, it may be noticeable by a slight discoloration of the white cloth used in wiping off the excess oil from the specimens.

#### DRAINING OR WORKING VISCOSITY

The working viscosity of a varnish can be determined by the variation in thickness of the dried film from one end of the metal strip to the other after dipping and drying. A strip of brass or copper 35 centimeters long, 4 centimeters wide and 0.127 millimeter thick is immersed in varnish at  $20^\circ\text{C}$ . to within one inch of the top or to a definitely marked line and the strip is withdrawn vertically from the varnish at a rate of 38 centimeters per minute. The specimen is then hung vertically and permitted to drain at room temperature. It is dried or baked, according to the type of varnish, until dry. The thickness is then measured at say 2, 7 and 12 inches from the top of the strip. The differences between the thicknesses at the three points give a measure of the variation as a result of draining and constitute the data indicative of the draining or working viscosity.

#### ABRASION RESISTANCE

Numerous methods have been devised for the determination of the relative ability of coatings to withstand abrasive action. Gardner<sup>11</sup> has described one procedure that has been used to a considerable extent. This test employs a glass tube about 6 feet long having an internal bore of 0.875 of an inch. The tube is supported vertically immediately above the coated panel. The specimen is placed at  $45^\circ$  to the vertical, and the abrasive material, No. 50 emery powder, is dropped through the tube from a funnel having a bore of 5 mm. In striking the surface the emery covers an area of about one inch in diameter. The flow of abrasive is maintained until the finish is removed from the surface upon which it is applied. By means of a reservoir at the top and a scale holding the vessel into which the emery falls, the operation can be made continuous. When the film has worn through, the flow is stopped and the weight of emery that has fallen is obtained as a relative value of the wearing properties of the film. If the panel is colored before the application of the varnish, the point of complete abrasion will be more clearly defined. Some experimenters have specified an Ottawa sand such as is used for testing cement.<sup>12</sup> For this material a rate of flow of one liter per 150 seconds has been found satisfactory.

The method described by Schuh<sup>13</sup> in which sand is blown by means of an air blast against a rotating disc on which the film has been prepared has also proven to be a good measure of this quality. Wacholtz<sup>14</sup> has also evaluated the abrasion resistance of paints and varnishes by means of sand directed upon the film. Van Heuckeroth<sup>15</sup> studied varnishes from this standpoint. He worked with sand and determined the number of kilograms necessary to cut through a thickness of 25 microns of film.

## ADHESION OF LACQUERS AND VARNISHES

It has been found quite difficult to formulate a satisfactory method of determining the adhesion properties of varnish and paint films that will be of general application. Many suggestions, however, have been tried and used with a certain degree of satisfaction. Gardner has described a fairly satisfactory method. The varnish or lacquer is applied, by brushing, spraying, dipping or spinning, to thoroughly cleaned plates of black iron, glass or other materials, 3 by 5 inches. A piece of silk cloth is placed on the specimen while it is still tacky, and pressed down firmly. The surface is then cut into strips one centimeter wide with a razor, after sufficient time has been allowed for the film to dry. Next the test panel is fastened in a suitable tension machine, and the strips of cloth, having been loosened at the top and folded downward, are then pulled directly along the surface. The adhesion of alternate pieces is measured in this fashion and quite consistent results may be thus obtained.

Peters<sup>16</sup> has observed that phenolic varnishes were unsatisfactory when used for priming coats on aluminum. This statement applies only to baking varnishes. The heating of the coating was found to impair the mechanical properties of the metal as well as causing the film to lift away from the surface.

Van Heuckeroth<sup>17</sup> has determined the adhesive properties of films by observation after the sand abrasion test. He merely noted whether or not the film had pulled away from the surface of the glass plate before it was cut through by the sand. This test, of course, gives no clue as to the relative degree of merit.

## DURABILITY OF VARNISHES

Many investigators have sought to obtain a test, or series of tests, which would indicate the probable durability of varnished surfaces. A sub-committee of the American Society for Testing Materials<sup>18</sup> found that there were several tests that gave good results in the hands of various investigators, but that the kauri reduction method for determining the elasticity or toughness was perhaps the most satisfactory procedure so far developed. Pulsifer<sup>19</sup> has also used the kauri reduction method and agreed it gave the best estimate of the durability of a coating.

The kauri reduction test is carried out by proportionally reducing the elasticity of the varnish with a solution of No. 1 kauri gum. A quantity of small broken pieces of "run kauri" is heated in the presence of twice its weight of spirits of turpentine. Only that grade of spirit which is volatilized between 153 and 170°C. should be used. The purified gum may then be dissolved in turpentine at 149°C., adding enough solvent to replace that lost during distillation.

It is next necessary to determine the non-volatile content of the varnish under examination according to the method outlined in a previous section. After this is done, add 100 grams of the varnish to an amount of the prepared kauri solution equal by weight to 50 per cent of the non-volatile matter in the specimen. Having mixed this preparation thoroughly, a small metal test panel is coated as described in the test for determination of drying time. When the film has dried, it should be possible to bend the panel over a 3 mm. rod, the coating being on the

<sup>16</sup> J. Peters, *Metallics*, 1932, 22, 1469, 1501; *Chem. Abs.*, 1933, 27, 2316.

<sup>17</sup> A. W. Van Heuckeroth, *Circ., Am. Paint, Varnish Mfrs. Assoc.*, 1930, 369.

<sup>18</sup> *Proc. Am. Soc. Testing Materials*, 1922, 22 (1), 375; 1923, 23 (1), 399.

<sup>19</sup> L. V. Pulsifer, *Proc. Am. Soc. Testing Materials*, 1923, 23, 282; *Chem. Abs.*, 1924, 18, 1203.

convex side, without cracking the film. For purposes of comparison it may be desirable to find the greatest percentage of kauri gum, calculated on the basis of the non-volatile material in the varnish, which may be added without rupturing the surface when bent over a 3 mm. rod.

Harrison<sup>20</sup> has observed the durability of some paints on wooden test panels that have been treated with preservatives repellent to termites. Red wood, western yellow pine and Douglas fir were impregnated with preservatives known as AC-Zol, Anaconda neutral, Bruce 5A, Halowax, Lignophol, Triolith, zinc chloride and zinc meta-arsenite. Three priming coats were used: aluminum bronze in mixing varnish, aluminum bronze in synthetic resin varnish and white lead-zinc oxide exterior paint which had been reduced with turpentine. White lead-zinc oxide raw linseed oil paint was used for the second and third coats. In addition the Halowax-treated wood received a Bakelite-type primer followed by the above-named top coats and finally by a white lead-zinc oxide Bakelite paint. The conditions of the tests after 6 and 12 months are given in detail. With the exception of Bruce 5A, all the preservatives permitted painting. The durability of the paint on zinc chloride treated wood was less than in the other cases. The first two priming coats mentioned gave better results than the last. The species of wood had no apparent effect.

Pearce<sup>21</sup> has made an extensive study of the relationships of physical tests and chemical composition with respect to durability. He has shown that the kauri reduction values are in good agreement with the results given by exposure data. Gardner<sup>22</sup> has presented the results of exposure tests upon several different samples of varnish, and also the results of various methods such as the kauri reduction test. This worker found that the kauri reduction test paralleled results obtained through actual service. In later work Gardner<sup>23</sup> found that the durability of spar varnishes was not improved by the addition of antioxidants such as pyrocatechol, quinol, heptene and two rubber accelerators.

Stearns<sup>24</sup> has also observed 20 typical varnishes using kauri reduction and regular exposure tests. For the older types of varnish the kauri reduction test does indicate durability, but among certain newer types it seems to fail, as for instance it has been reported in the case of one type of phenolic resin, better durability was associated with lesser kauri reduction values.

Levy<sup>25</sup> has ascertained that the kauri reduction test does not give reliable indication as to durability in the case of varnishes made of alkyd and some phenolic types of resins. Information on embrittlement may be obtained by using arc-lamp irradiation. This method was employed by Wilson<sup>26</sup> in connection with pure sheet rubber as a substratum for his varnished test pieces.

Kolke<sup>27</sup> determined the durability of coatings on phosphatized and untreated iron. When the panels were prepared half the metal surface was sanded, and then half the sanded portion and half the unsanded portion were phosphatized. The coatings used were shellac, bituminous varnish, synthetic resin spirit varnish and synthetic resin-tung oil varnish. These were exposed to salt water spray for four weeks. In general the durability was greatest on the sanded phosphatized surfaces, next on the phosphatized only, next on sanded and last on the untreated surfaces.

## KAURI-BUTANOL TEST

The kauri-butanol test is frequently employed to evaluate various solvents which might be employed in varnishes. Briefly, the test consists of titrating 20 grams of gum kauri solution with the solvent to be tested in a 200 cc. Erlenmeyer flask. The kauri solution as used here is prepared by dissolving 100 grams of gum kauri in 500 grams of normal butanol. The end point is reached when the normally clear liquid acquires a slight turbidity. This may be determined by placing a printed page beneath the flask, and noting when the print, as viewed through the solution, just becomes blurred. The number of cubic centimeters of solvent required to produce this end point is the kauri-butanol value of the solvent. When the kauri solution is properly prepared, titration with C.P. benzene will give a value of 100.

Sweeney and Tilton<sup>22</sup> have reported on the results given by this procedure as applied to hydrogenated solvent naphthas.

## EXPOSURE TESTS

Exposure tests are designed to secure information concerning the probable durability of a varnish if it were in actual service. The test is employed to give results more readily than would be the case if the material were put in actual service. The exposure is so made as to subject the materials, if possible, to the most severe conditions found in the service for which it is intended. Thus one specimen may be subjected to heat and cold alone, another sprayed with hot and cold water, and still others may be weathered under normal conditions of rain, wind, snow and sun.

Walker<sup>23</sup> has pointed out the importance of position in weather tests. He finds that panels should be set at 45° to the horizontal facing south in the latitude of Washington, D. C. This angle should be varied according to geographical position and should be the same as the latitude of the locality.

Arnold<sup>24</sup> has described some exposure tests made in the woods of Brazil over a period of a year. All varnishes of the ordinary type showed stickiness for considerable time. Varnishes containing synthetic resin did not yield this unfavorable result.

Gardner<sup>25</sup> has given a description of accelerated laboratory tests for paints and varnishes. Exposure to ocean air showed phenolic and modified phenolic oil varnishes to give generally satisfactory results as compared with many coatings. Rapid failure was shown by sulphur-treated varnishes, lead tungstate liquids, boiled linseed oil, gloss oil and a water-resistant rubber varnish.

Van Heuckeroth<sup>26</sup> gives a number of results for various resin finishes which were flowed out upon black iron panels that had previously been primed with an oleoresinous coating pigmented with equal parts of Indian Red and zinc chlorate. These coatings were baked for two hours at 240-250°C. and then rubbed. The panels were duly exposed on racks facing south at 45° to the vertical. The number of days for the first and also for the final failure were noted. The latter period was arbitrarily set at the time when the film did not protect 50 per cent of the surface.

## ACCELERATED WEATHERING TESTS

Since the accumulation of data by normal exposure is extremely slow, there has been much interest in the development of accelerated tests designed to secure comparative results in a relatively short time. Gardner<sup>22</sup> has reviewed the details of the developments of this type of test. As innumerable combinations of artificial conditions are possible only a few of the fundamental principles involved in accelerated testing cabinets will be described here.

**Carbon Arc Exposure Cabinet.** In this cabinet, panels 5 by 10 inches with specimen coatings are set upon a flexible rack. These are exposed to two carbon arc weatherometers which revolve once every thirty minutes, being followed by alternating sprays of water. The panels are placed approximately 8 inches from the lamp globes and reach a temperature of 140°F., after which they are cooled to approximately 70° by the water. This accelerated test obtains, in about 300 hours, results that would require at least three to six months under standard conditions of service.

**Mercury Tube Test Cabinet.** In a cabinet of this type use is made of a quartz tube mercury vapor lamp. The source of light is mounted horizontally at the axis of a drum revolving horizontally. The panels to be exposed are placed upon the inside of the drum in such a way that the lower section may be immersed in water.<sup>24</sup>

## FLEXIBILITY

The following procedure has been found to be of considerable value in classifying varnishes as to flexibility. An H28 gage aluminum plate is coated to such a thickness that one ounce of varnish, based on the dry weight; would be used per square yard. The plate is hung in a well-ventilated drying room, after which it is baked at 100°C. for two hours and finally allowed to cool for half an hour. It should then be bent at an angle of 180° over a quarter inch rod. A durable varnish will exhibit no cracks after this treatment.

Schuh<sup>25</sup> has used a mandrel test for flexibility in which he has elaborated slightly on the customary procedure. His instrument permitted metal panels up to thicknesses of  $\frac{1}{16}$  inch to be bent about any one of six rods varying in diameter from  $\frac{1}{8}$  inch to 1 inch, in such a manner that the panels followed closely the contour of the mandrels. The smallest diameter bend permitted without fracture is then a measure of flexibility.

## GLOSS MEASUREMENT

Reference should be made to the discussion of this subject in Chapter 69, as the fundamental principles embodied in the determination of the gloss of a varnish film are the same as for the surface of laminated or molded phenolic materials. Bolme<sup>26</sup> has made some special tests which he believes are of considerable practical value. His method is based upon comparisons between the reflection given by the specimen surface as contrasted with those of a series of standard coatings of nitrocellulose lacquer. The latter are prepared by mixing a flattening paste with a clear

lacquer. The reflected object appears as a translucent white field with black cross bars, and the reflected field can be held in definite relation to the standards and specimen.

#### HARDNESS OF VARNISH FILMS

Gardner and Parks<sup>27</sup> have made a review of the older methods of testing the hardness of films, including the Laurie-Baily, the Clemens and the weighted pencil point scratch method. They have given photographs of the scratches produced together with a tabulation of the results obtained.

Walker and Steele<sup>28</sup> of the U.S. Bureau of Standards have determined hardness by the use of a swinging beam pendulum. The apparatus employs a beam whose fulcrum is a ball, pivoting on a specimen of the varnish film prepared on a base plate. The method consists of oscillating the beam through a chosen amplitude while the ball is resting on the specimen film. The time required for the pendulum's amplitude to decrease to one half its original value is compared with the same quantity when the ball of the balance is resting on a piece of smooth glass as a standard surface. Van Heuckeroth<sup>29</sup> has also used this type of instrument.

Laurie<sup>30a</sup> has employed a device constructed much after the manner of a Westphal balance. The long arm carries a point on the underside and a pan on the top. The test film is prepared on glass. The weight required to scratch the film is noted as well as the nature of the scratch. When the scratch is ill-defined or can be erased by rubbing, the film is harder than the crystal used as the scratching medium.

Wolff has suggested a method similar to Laurie's procedure except that a knife blade is substituted for the point. The sample is carried on a car and moved at a definite speed under the blade, and the weight required to mar the surface is noted. This test requires that the film be of uniform thickness.

Wolff and Wilborn<sup>30</sup> have pointed out some of the merits of the pencil method of determining hardness of films and have also outlined a way of overcoming the difference in pressure applied when making the test. The process involves placing the varnished panel to be tested in one pan of a balance, and loading the other pan with a definite weight. Only sufficient pressure is exerted during the test to ensure equilibrium. The surface is consequently held up against the moving point by a definite force. In a revised method outlined by Wilkinson<sup>31</sup> pencils of different grades were drawn across the film until one hard enough to cut the film was found. It was stated that the results were practically independent of the pressure used in applying the pencil point.

Löwa<sup>32</sup> has measured the difference in hardness of films which had been pigmented with white lead, ferric oxide, zinc oxide, titanium oxide and graphite respectively. Marked differences were observed between the films kept inside and films exposed to the weather at 45° facing south. Of the indoor films the graphite paint showed the greatest loss in hardness, while in exposure tests it suffered the least.

<sup>32</sup> A. Löwa, *Farben Ztg.*, 1932, 38, 100.

Wilkinson<sup>42</sup> has described a modified form of the swinging-beam hardness apparatus in connection with a discussion on physical examinations of paints.

Sward<sup>43</sup> has proposed an apparatus for testing surface hardness that is composed of rocker arms carrying a weight, a means of shifting the center of gravity of the weight, a pendulum operated by the rocker arms from a point directly above the weight, and a scale co-operating with pendulum for measuring the angle of deflection. The apparatus is rocked backward and forward and the angular movement noted. The harder the surface, the greater will be the angle of movement.

Sheppard and Schmitt<sup>44</sup> have given a detailed description of a method used to determine resistance to scratching, which has the advantage of giving quantitative results. It was employed in connection with studies of cellulose derivatives but it is capable of general application. The equipment consists of a scratch dynamometer and an instrument for observing the cut. The dynamometer can be arranged to give a single scratch, made by an increasing load or, if preferred, a series of scratches, each employing a constant pressure. The width of the cut may then be measured, and it is also possible to accurately observe its appearance.

Banks<sup>45</sup> has recommended that a moderate sized sample of varnish be placed in a glass container and examined from time to time for the formation of a skin. Preferably, the specimen should be kept in a dark room to simulate the conditions under which it would be stored in the usual metal can.

#### DIELECTRIC STRENGTH IN DRIED STATE

A dielectric strength test has been formulated to determine the practicability of a varnish for impregnating cloth or paper. While the test is only relative and does not give the actual dielectric strength of the varnish alone, it does give the dielectric strength of the treated material as normally used. Specimens of kraft paper 20 cm. square and 0.076 mm. thick are impregnated by double dipping, once in each direction in accordance with the procedure given for the drying time test. The specimens should be dried for a period exceeding several times that required for the determination of the drying time. After being dried, the sample is then placed between electrodes which should be of circular form, two inches in diameter. The edges of these discs must be rounded, preferably to a radius of 0.75 cm., as failure will otherwise take place around their circumferences and give misleading results. The transformer used should be of such a type that the potential may be raised at the rate of 500 volts a second.

The dielectric strength should be determined under three separate conditions:

- (a) At room temperature (approximately 20°C.) in air.
- (b) At 75°C. in air.
- (c) At room temperature on specimens which have been immersed in water for a period of 24 hrs.

If the tests are also run under oil at 20 and 75°C. this fact should be definitely stated as results obtained in oil will not agree with those found when the specimen is surrounded by air.

Since the dielectric value of the impregnated material does not appear to bear very direct relationship to the strength of the paper employed it is not usual to determine this value before treatment.

<sup>42</sup> J. A. F. Wilkinson, *J. Oil, Colour Chem. Assoc.*, 1932, 15, 259; *Chem. Abs.*, 1933, 27, 197.

<sup>43</sup> G. G. Sward, U. S. P. 1,938,752, Nov. 21, 1933; *Chem. Abs.*, 1934, 28, 918.

<sup>44</sup> R. E. Sheppard and J. J. Schmitt, *Ind. Eng. Chem. Anal. Ed.*, 1933, 4, 302.

<sup>45</sup> L. M. Banks, *Circ., Am. Paint, Varnish Mfrs. Assoc.*, 1932, 432; *Chem. Abs.*, 1933, 27, 614.

In determining the dielectric strength of dipping, brushing and spraying varnishes it is desirable that they be tested under as many conditions as possible. This is due to the fact that a comparison of the values given by a single varnish under various treatments is of importance.

#### DIELECTRIC STRENGTH IN THE LIQUID STATE

If a coating is to be used for insulating purposes an examination of its dielectric strength as a fluid becomes of interest since such procedure will indicate the presence of water or foreign matter in the material. However, this test can not be applied to varnishes whose solvents are poor insulators as for example alcohol.

The container used for this work should be a oil test cup made of a material having high dielectric strength. The electrodes are preferably flat discs one inch in diameter and so mounted in the cup that a gap of 0.10 inch can be accurately maintained between them. The electrodes should be at least 1.5 cm. below the surface of the varnish during the test.

#### RESISTIVITY

**I. Volume Resistivity under Normal Conditions.** In order to determine the volume insulation resistance of varnish for dielectric purposes, the samples can be prepared on copper or brass strips such as are used for the preparation of the specimens for drying time examination. The test pieces, however, must be dipped and dried twice so as to develop a greater thickness of coating. The final drying period should be the same length as that employed for the preparation of the samples under dielectric strength. Electrodes two centimeters in diameter may then be painted, using a conducting coating, such as aluminum bronze, at various places over the surface, no two electrodes being placed nearer than three centimeters on centers. The resistance between each of these electrodes and the brass or copper plate can then be measured by a galvanometer.\* Knowing the area of the electrodes, the thickness of the varnish film, the current flowing through the varnish as indicated by the galvanometer circuit, and the current flowing through a standard resistance, say, one megohm, the resistivity per unit volume may be determined.

The calculation of the volume resistivity of the film is made as follows: The volume resistance,  $R$ , in ohms, is calculated from the equation

$$R = \frac{MDS}{D'S'}$$

where

$M$ =value of calibrating resistance in ohms.

$D$ =deflection of galvanometer, in any system of units, with the calibrating resistance only in the circuit.

$S$ =shunt ratio when calibrating resistance is measured.

$S'$ =shunt ratio when sample is being measured.

$D'$ =deflection of galvanometer with sample in the circuit in the same units as " $D$ ."

\* *A.S.T.M. Tentative Standards, (D267-32T), 1932, 885.*

The unit resistivity in ohms per cubic centimeter,  $C$ , may be calculated from the formula

$$C = \frac{RA}{T}$$

where

$R$ =volume resistance in ohms as found from the preceding equation.

$A$ =area of the small painted electrodes in square centimeters.

$T$ =thickness of the varnish coating in centimeters.

This does not take into consideration the edge effect, but since the film is very thin as compared with its area the error involved is scarcely worth taking into account. Certainly the proportionate magnitude of discrepancy due to this cause is less than that introduced in the physical measurement of the thickness of the varnish film.

**II. Surface Resistivity under Normal Conditions.** The determination of the surface resistivity of dried varnishes differs from the preceding examination in some particulars. The specimen must be prepared on a non-conductive base such as glass or fused quartz. Two metal strips, 10 cm. long, spaced parallel to each other at a distance of 1 cm., are placed upon the coating. In some cases it may be found more convenient to press strips of tin foil into the varnish before drying to insure intimate contact with the electrodes. Employing a galvanometer circuit, the total resistance between the electrodes may again be calculated from the formula given in the preceding section.

$$R = \frac{MDS}{D'S'}$$

Then the unit surface resistivity,  $\rho$ , or the resistance between the two opposite sides of a square will be obtained from the expression

$$\rho = \frac{RL}{B}$$

where  $R$ =resistance in ohms as found above.

$L$ =length of the electrodes in centimeters.

$B$ =distance between electrodes in centimeters.

It is often necessary to measure the effect of humidity on a varnish film at moderate temperatures since this condition is frequently found in service and also because varnishes will show considerable differences when subjected to moist atmospheres. While complete equilibrium is not reached in all cases even after an exposure of four days to humid conditions, the resistivity has been so lowered by such treatment that it gives a good measure of the insulating property of the film. Hence after the samples are prepared they can be exposed to the desired degree of moisture in closed vessels for the length of time desired. Proper conditions of humidity may be produced by choosing the appropriate salts for use in the desiccator, or by selecting a sulphuric acid-water solution of the proper density. The salt solutions are the more satisfactory since the humidity is not affected by the conditions of moisture of the specimens. A supersaturated solution of common salt,  $\text{NaCl}$ , will give an atmosphere of 75 per cent relative humidity, while a 90 per cent relative humidity may be obtained by use of a solution of potassium nitrate in water having an excess of salt present. Or, if one cares to do so, he may obtain

any desired condition by mixing dried air and saturated air in different proportions by a bubbling process.

The determination of the effect of humidity on the surface resistivity of varnish films can be measured while the film is exposed to the humid conditions if proper care is exercised. The samples, having been prepared as mentioned in the test for surface resistivity under room conditions, are placed in closed vessels having the desired humidity. By running leads into the receptacle through carefully insulated sections, the resistivity measurements may be taken as desired. Care must be used, however, to protect the surfaces on the inside of the humidity chamber so that the measuring leads will not take up moisture. If the inside of the container between these leads is well coated with crude ceresin or ozokerite, little difficulty will be experienced in making the measurements, and error due to leakage will be minimized.

#### POWER FACTOR AND DIELECTRIC CONSTANT OF VARNISH FILMS

The specimens for use in power factor measurements are prepared on metal strips in accordance with the methods used for drying time tests. Electrodes can then be placed on the surface. A convenient method is to apply tin foil with a small quantity of vaseline or to paint the conductive areas on the sample with aluminum bronze. It is only necessary to apply one electrode, however, as the copper or brass base plate will serve for the other side of the circuit. The size of the terminals should be adjusted to yield the capacitance desired in order to make the power factor measurements with the apparatus available. Diameters of two centimeters or more will ordinarily give adequate capacitance. The usual methods of measuring power factor at frequencies of 60 cycles, 1000 cycles and 100 to 1500 kilocycles have already been described in Chapter 69.<sup>44</sup>

#### WATER ABSORPTION OF VARNISHES

Stoppel<sup>45</sup> has carried out water absorption tests on carefully prepared panels of basswood protected with four coats of various varnishes, the elasticities of the films having been previously determined by the kauri reduction method. It was stated that the permeability of the film decreased with increased thickness, that it decreased with an increase in the proportion of resin in the varnish and that it decreased as the whitening of the film decreased when the usual water test was employed. This worker also showed that a varnish which was highly impermeable to water when fresh lost this property upon exposure. It would appear that the permeability of all varnishes to water decreases during exposure until cracking occurs, at which time it obviously would increase very rapidly. Water apparently does not penetrate a varnish film through pores but is dissolved and then absorbed by the under body, hence whitening of a film may be attributed to supersaturation of the coating.

Van Heuckeroth<sup>46</sup> has determined the water permeability of the films which he studied by two methods. The coatings were first prepared by spinning lacquer upon amalgamated tin panels, drying and then stripping off the film. By his first method, 10 grams of water were placed in a four-ounce screw-cap container. The tops of the jars were then cut out so as to form an opening 3 cm. in diameter. The film was extended over the top of the jar and the perforated cap screwed into place. The joint between the cap and the jar was sealed with wax, and the

<sup>44</sup> A.S.T.M. *Tentative Standards*, (D150-34T), 1934, 34.

<sup>45</sup> E. A. Stoppel, *Proc. Amer. Soc. Testing Materials*, 1924, 24, 455; *Chem. Abs.*, 1925, 19, 1783.

<sup>46</sup> A. W. Van Heuckeroth, *Circ., Am. Paint, Varnish Mfrs. Assoc.*, 1930, 369.

containers were placed in pint jars containing approximately 50 cc. of concentrated sulphuric acid. The amount of moisture passing through the film was then determined by periodic weighings.

In the second test, the migratory tendency of the water was reversed. Ten grams of calcium chloride in jars were put in external containers in which 50 cc. of water had been substituted for the acid. These inner jars were also weighed every 24 hours to determine the amount of water absorbed by the salt. Neither method showed a marked change of weight but noticeable differences were found when the inner jars contained calcium chloride and were surrounded by an atmosphere of 100 per cent humidity at 35°C. Gettans<sup>12</sup> has measured the penetrability of varnish films in the same manner for the purpose of evaluating coating materials used for the protection of works of art. This worker found alkyd resins quite impermeable and satisfactory for such purposes.

Grün<sup>13</sup> has also made determinations employing a permeable disc, covered with the protective coating, subjected to the action of water at elevated pressures. Wray and Van Vorst<sup>14</sup> have studied three different methods for determining the penetration of moisture through paint films and compared the results obtained. The most valuable information was obtained by measuring the permeability of the coatings individually. This was done by stretching the films across the tops of Petri dishes which had been partially filled with activated alumina. The Forest Products Laboratory method which was also used consisted of applying various paints and varnishes to selected panels of yellow birch 4 by 8 by 5/8 inches which, after drying, were weighed and placed in an atmosphere of 95 per cent humidity at 77°C. for two weeks, when any increase in weight was noted. The third procedure tested employed circular panels of coated wood, 5.3 cm. in diameter, which were fastened to the tops of jars in the same manner as if the film alone was used as a medium of separation between the two atmospheres. Edwards<sup>15</sup> has written a discussion of the results of Wray and Van Vorst in an attempt to interpret moisture permeability measurements. He stated that there are many advantages in determining moisture permeabilities of paints by films alone and then, with the results from this work at hand, the more complex phenomena observed with films on wood may be interpreted.

Morrell<sup>16</sup> has discussed the factors affecting the absorption of water by varnish films. He has suggested that it is a function of the composition, manner of drying and aging of the film. Absorption is retarded by the presence of salts in the water, even in small amounts, as the difference in effect of tap and distilled water may be detected. After drying, the film will show a larger absorption value upon repeated treatment. Alternate exposure to air and water appears to reduce the amount of absorption, due to oxidation and polymerization. An elastic water-resisting varnish showed 0.3 per cent absorption in 1 day, 0.4 per cent in 2 days, 1.9 per cent in 5 days and 2.8 per cent in 9 days, and at the end of this period still remained clear. Varnishes with low water-absorption show, however, a tendency to bloom if the superficial drying of the film is pronounced.

Wilkinson and Figg<sup>17</sup> have determined the absorption of varnish films when prepared on aluminum sheets. The coated plates were suspended in a hot water bath and after the required time had passed they were removed, dried carefully

<sup>17</sup> J. A. F. Wilkinson and E. F. Figg, *J. Oil, Colour Chem. Assoc.*, 1924, 7, 232; *Chem. Abs.*, 1925, 19, 1954.

and weighed. It was found that the thin films absorbed a greater amount of moisture than the thicker ones when calculations were based on the percentage of weight increase. The absorption was found to be the same, however, irrespective of thickness of film, when the result was based on quantity of moisture per unit area, provided the films were newly prepared. Absorption increases with the temperature and is approximately twice as rapid at 40°C. as it is at 20°C. Measurement of the thickness of the films showed that the volume of the film increased by an amount equal to the quantity of the water absorbed. It may be pointed out that the curves showing the progress of this action are parabolic, and that absorption will therefore theoretically proceed indefinitely; practically, however, the distended varnish cells will eventually rupture, thus destroying the coating.

Jaeger<sup>57</sup> has studied the porosity of films. The surface to be varnished was coated, first, with a metallic salt and, after it dried, a coat of varnish applied. When the finish dried the upper surface was treated with an aqueous solution of a reagent which gave an intense color reaction with the metallic salt under the protective coating. In this way minute pores can readily be detected in transparent films on opaque surfaces. In a similar fashion opaque films can be investigated by using a transparent base such as glass. Oil varnishes were shown to be distinctly porous. This test is of assistance in interpreting results obtained on the permeability of films by other methods.

#### VARNISHES AS PROTECTIVE COATINGS

No attempt will be made in this section to give a comprehensive outline of the various applications of varnishes in which they are used as protective coatings. On the contrary, only a few of the special uses will be mentioned. The testing of coatings intended for such purposes can be carried out by means of the several methods already described in this chapter and in addition various investigators have outlined and employed special tests for the coatings in which they have been particularly interested. For example, the tests which have been used for electrical refrigeration coatings have been outlined.<sup>58</sup> These include examinations for water resistance, flexibility, adhesion, grease resistance, resistance to yellowing, mar resistance and opacity of the paint or varnish film. Tests would seem to indicate that synthetic resins used in protective coatings offer the advantages of faster and better drying and also greater durability.

#### APPLICATIONS FOR PIPE AND TANK PROTECTION

Gardner<sup>59</sup> has pointed out the results of research in which a semitransparent coating for pipes was sought. It was found that raw oil paint dried too slowly, but that the durability was high although oleoresinous varnishes had poor durability if the oil content was low. Pigmentation and a high percentage of tung oil contributed to the durability but at an increased cost. For heat-treated oils certain mixtures of drying oils gave good results, especially when combined with highly dispersed zinc chromate. Synthetic resins were highly durable and resistant. Asphalt varnishes failed when exposed to the sun and nitrocellulose compositions involved a fire hazard but had many mechanical advantages. Kimpflin<sup>60</sup> has discussed the various applications of synthetic resins to pipe and oil tank coatings. It was found that paints made from synthetic resins were satisfactory for protect-

<sup>59</sup> H. A. Gardner, *Chem. Met. Eng.*, 1931, 38, 402.

<sup>60</sup> G. Kimpflin, *Peintures, pigments, vernis*, 1931, 8, 1606, 1629; *Chem. Abs.*, 1932, 26, 1139. *Inst. Metals*, 1925, 32, 551; *Chem. Abs.*, 1925, 19, 1932.

ing crude oil tanks both ashore and in tankers whereas other materials so far on the market were quite unsatisfactory. This worker also stated that phenol synthetic resin finishes will protect water pipes against the action of chlorine.

Gill<sup>61</sup> has given a discussion of the general status of pipe line protection. It was stated that the impermeability of coatings depends upon their resistance to deterioration from chemical and bacterial action, the freedom from capillary pores and the resistance to mechanical distortion. The latter of these conditions is considered the most important.

#### FINISHES AS AIRPLANE COATINGS

Whitmore<sup>62</sup> has outlined the properties which a good coating should have for airplane service. These requirements are high resistance to water-permeability, the use of pigments which tend to passivate metals and prevent corrosion, the absence of pigments of alkaline reaction, good adhesion to metals which may not be chemically clean and high resistance to impact and bending even after exposure. McCloud<sup>63</sup> has also listed the requirements of such coatings. It was stated that they should have good appearance and adhesion and also prevent the corrosion of light metal alloys. These coatings were evaluated according to the change in tensile strength and percentage of elongation as exhibited by coated test bars of various metals after exposure. Results of such tests of various coatings with particular reference to variations in the priming coat on duralumin, magnesium alloys and steel, showed a zinc chromate-synthetic resin primer to exhibit desirable characteristics. This first coat with an aluminum lacquer top coat gave outstanding protection. Edwards and Wray<sup>64</sup> have discussed the protection of aluminum by means of coatings. For certain purposes the yellowing of an ordinary varnish makes its use questionable as a transparent finish. Some of the newer synthetic resin varnishes, as, for example, those of the glycerol phthalate type, showed very satisfactory results over a substantial period. This group was shown to possess even greater durability than cellulose lacquers, and the adhesion to aluminum surfaces was excellent. Certain of the vinyl resins also gave satisfactory performance.

#### RESISTANCE OF COATINGS TO DISCOLORATION

Van Heuckeroth<sup>65</sup> has observed the yellowing of a large number of lacquers made using resin bases. Films of the lacquers were prepared in the same manner as for tensile strength tests and strips of the films were enclosed in cardboard folders so that a circle of the film 2 cm. in diameter was exposed while the balance of the piece was protected. Films were subjected to radiation from quartz lamps for two hours while the cabinet was maintained at a temperature of 70°C. The change in color of the films was determined by means of a varnish colorimeter.<sup>66</sup> He noted that many resins showed a tendency to blacken instead of yellow and also that plasticizers of the phthalate type exhibited but slight yellowing.<sup>67</sup>

<sup>66</sup> A. W. Van Heuckeroth, *Circ., Am. Paint, Varnish Mfrs. Assoc.*, 1930, 367.

<sup>67</sup> As to the possibility of decreasing the yellowing tendency of varnishes using synthetic resins, B. Peters (British P. 295,941, Aug. 8, 1928; *Chem. Abs.*, 1929, 23, 924) has stated that by addition of a small proportion, about 0.5%, of a strong organic or inorganic acid, acidic salt or nitrate soluble in the varnish, the fastness to light can be greatly increased. Suitable substances include trichloroacetic, perchloric, hydrochloric, sulphuric, nitric and nitrous acids, aluminum, ferric and cupric chlorides, bisulphates and the nitrates of calcium, bismuth, thorium, uranium and cobalt.

D. C. Duncan, W. P. Davey and D. R. Wiggam (*Ind. Eng. Chem.*, 1931, 23, 904.) have investigated the coloring of lacquer films under the action of ultraviolet light.

**Appendix**  
**Trade Names List**

## Trade Names List

Synthetic resins are known and sold commercially under various trade names which to the uninitiated give little clue as to their chemical nature and uses. The accompanying compilation lists the trade names of synthetic resins and plastic materials, showing wherever possible their chemical type. Included in the list are the names of fabricated resin products as well as those of the original molding, casting and coating compositions. Related products, such as cellulose, casein, asphalt and natural resin compositions, are also represented in part—especially if the materials are well known or the name is similar to that of a synthetic resin composition.

The trade names, arranged alphabetically,<sup>1</sup> are followed in turn by abbreviations designating the chemical type or composition (e.g., phenol-formaldehyde resin); the form and use (such as soluble varnish resin, molding composition); the manufacturer or distributor, with addresses; and references giving the source of the information.<sup>2</sup>

### ABBREVIATIONS

#### Composition

B	Inorganic
C	Casein
CA	Cellulose acetate
D	Resin used as ingredient
F	Fabricator's trade name
GP	Glycerol-phthalic anhydride
PF	Phenol-formaldehyde
Px	Pyroxylin
RPG	Rosin-phthalic anhydride-glycerol
SR	Synthetic resin
UF	Urea-formaldehyde
V	Viscose
W	Wood fiber
X	Miscellaneous
?	Nature not known

#### Forms, Uses

f	Sheets, rods, tubes
l	Laminated
m	Molding composition
s	Soluble type (for coatings and impregnation)
t	Turnery type (cast and machined articles)
SG	Safety glass
P	Packaging material

<sup>1</sup> Initials are filed under first letter without regard for "and," periods or hyphens. Compound names, with or without hyphen, are indexed under first name.

<sup>2</sup> Some of the items in the list have been obtained from the advertising pages of the references given. Where no source is indicated, the information has been ascertained from trade announcements and catalogs or by private communication.

It will be noted in the source column that certain references are composed of a letter or letters joined to a number by a hyphen. These indicate a specific source that is fully given in the key. References to books are given by a group of letters (defined in the key) followed immediately (without a hyphen) by the page number. Thus, APV-1 indicates that the source of the material is American Paint & Varnish Mfrs. Assn. Circular 369; whereas KPM278 designates Page 278 of Kausch's "Handbuch der künstlichen plastischen Massen."

# Subject Index

## A

- Abietates of monohydric alcohols, preparation of, 797, 798, 799
- Abietene, from abietic acid, 780
  - , reaction with sulphur, 1205
- Abietenesulphonic acid, 780
- Abietic acid, alkylating agents for, 805
  - , chlorinated, in shellac substitutes, 1139
  - , condensation with high-boiling ester, 800
  - , decarboxylation of, 780
  - , diene system in, 764
  - , esterification of alkylene oxides with, 823
    - , — phenol with, 397
    - , — phenol-alcohols with, 399
    - , — wax alcohols, 814, 815
  - , extraction from waste liquor, 753, 755
  - , formation of the triabietate with glycerol, 792
  - , hydrogenation of, 807
  - , in rosin, 764, 765, 766
  - , neutralization of glycerylamine with, 804, 805
  - , nitration, resins from, 781
  - , nitriles of, 804
  - , reaction with maleic anhydride, 844, 845, 856, 857
    - , — sulphur, 1205
    - , — tetrahydronaphthol, 800
    - , structure of, 764, 856
    - , synthesis of, 765
    - , use, alkyl-modified urea-aldehyde resin 662
- Abietic acid esters, as plasticisers, 823
  - , hydrogenated, plasticisers, 1125
  - , properties of, 797, 798, 829
- a*-Abietic acid, preparation, 767
- Abietic anhydride, from rosin, 767, 799
  - , reaction with phenols, 800
- Abradants, preparation of, 887
  - , use of alkyl resin in, 907
- Abrasion resistance, chloroprene rubber, 158
  - , chlororubber, 1125
  - , varnish films, 19
  - , varnishes, tests for, 1366
- Abrasive cements, 532
- Abrasive cloth, from polystyrene, 251
- Abrasive paper, from polystyrene, 251
  - , urea resin, 646
- Abrasives, alkyl resin binders for, 986
  - , chlororubber-modified phenol-aldehyde resin binder, 1126
  - , cumarone resin in bonding material for, 135
  - , fillers, 1251, 1275
  - , phenol-aldehyde resin, binder for, 318, 460
  - , polystyrene bonding agent for, 251
  - , polyvinyl acetate adhesive for, 1028
  - , use, finishing moldings, 1380
- Abrasive wheels, 485, 487, 1100, 1286
  - , treatment with pentachloronaphthalene, 1152
- Absorption bands in spectrum of acetaldehyde vapor, 494
- Absorption spectra, phenol-formaldehyde resins, 312, 313
- Absorption, total, of laminated materials, 1844
  - , water, tests for, 1843
- Acacia, gum, use in urea-formaldehyde resins, 601
- Accelerated weathering tests, for varnishes, 1370
- Acceleration of oxidation by driers, 784
- Accelerators, use of, in alkyl resins, 911
- Acceptor, hydrogen, 254
- Acetoides gum, in grinding wheels, 536
- Accumulators, types of, 1309, 1310
- Acenaphthalene-formaldehyde resins, preparation of, 265
- Acenaphthene, action of acetic anhydride on, 265
  - , condensation with formaldehyde, 265
  - , — olefins, 194
- Acenaphthylene, polyacenaphthalene from, 260
- Acetaldehyde, absorption bands in spectrum of, 494
  - , acetalcohol from, 489, 498
  - , acetylalcohol from, 499
  - , acidity of commercial, 497
  - , action of aromatic hydrocarbons on, 263
    - , — pea meal on, 494
    - , — sodium hydroxide, 1032
  - , aldolization of, 497
  - , autocondensation, 489, 499
    - , by oxidation of alcohol, 754
  - , by-product, preparation of divinyl ethers, 1008
  - , Cannizzaro reaction, 489
  - , catalysts in production of, 496
  - , condensation reactions over oxide catalysts, 495
  - , condensation with acetone, 544
    - , — acetophenone, 557
    - , — ammonium cyanate, 591
    - , — aniline, 689, 700, 702, 703, 705, 706, 709, 711
    - , — casein, 732
    - , — cinnamic aldehyde, 494
    - , — cresidine, 701
    - , — cyanamide, 494
    - , — cyclohexanone, 559
    - , — ethyl acetoacetate, 546
    - , — ethylamine, 705
    - , — formaldehyde, 546, 900
    - , — furfural, 521
    - , — hydroxyethylamine, 705
    - , — isopropylamine, 705
    - , — methyl ethyl ketone, 544
    - , — mesityl oxide, 551
    - , — mixed hydroxytoluic acids, 374
    - , — naphthylamines, 700, 708
    - , — polyvalent phenols, 372
    - , — p-vinyl, 741
    - , — sulphonamides, 61
    - , — tar oils, 368
    - , — thiourea, 637
    - , — toluidine, 700, 701, 703
    - , — urea, 642
    - , — xylidines, 703
  - , conversion to acetalcohol, 494
  - , decomposition by ultraviolet rays, 494
  - , differentiation from aldol, 497
    - , from acetylene, 380, 495, 496, 703
    - , from divinyl ether, 1011
    - , from ethyl alcohol, 496, 497
    - , from ethylidene diacetate, 1019
    - , from lactic acid, 1003
    - , from monochloroethylene, 1054
    - , from sulphite waste liquor, 380
    - , from vinyl esters, 1032
  - , gaseous, reaction with phenol, 382
  - , manufacture of, 496, 497
  - , metaldehyde from, 489
  - , mild alkalies as catalysts in aldolization of, 489
  - , modifier, urea-formaldehyde resins, 671
  - , photolysis of vapor, 494
  - , polymeric, oxidation of, 507
  - , polymerisation of, 505
  - , polymerised with casein glue, 495
  - , reaction with acetic anhydride, 1016
    - , — ammonia, 686
    - , — aniline-sulphonamide, 715, 716
    - , — aryl thioureas, 671, 672
    - , — cresol, 330, 331
    - , — *p*-dimethylaminobenzaldehyde, 509

- Acetaldehyde, reaction with dimethyldihydroresorcinol, 497
- , — ethyl alcohol, 495
  - , — formaldehyde, 495
  - , — furfural, 519
  - , — guanidine, 681
  - , — hydrogen sulphide, 1180
  - , — hydrolysed vinyl ester-aldehyde resin, 1066
  - , — naphthols, 283
  - , — phenol, 283, 380, 382
  - , — phenol-o-benzoylbenzoic acid resins, 376
  - , — 5-phenyl-2,4-pentadienal-1, 494
  - , — polyvinyl alcohol, 495, 1060, 1061, 1062
  - , — resorcinol, 278
  - , — sodium vinylacetylde, 151
  - , — sulphonated cresol-castor oil mixture, 421
  - , — tar oils, 407
  - , — thiophenols, 377
  - , — urea and resorcinol, 677
  - , — vinyl compounds, 1064, 1065
  - , — relation to vinyl alcohol, 1054
  - , — resinification of, 489-497
  - , — separation from reaction mixture, 496
  - , — solvent, polyvinyl acetate, 1025
  - , — synthesis of, 178, 496
- Acetaldehyde-amine resins, 701
- Acetaldehyde-aniline product, rubber accelerator, 705
- Acetaldehyde diphenyl acetal, formation of, 1009
- Acetaldehydedisulphonic acid, 419
- Acetaldehyde-ethylenediamine, 709
- Acetaldehyde-formaldehyde condensation product, 495
- Acetaldehyde-furfural condensation, 521
- Acetaldehyde-phenol reaction, 283, 404, 407, 418, 419, 532
- Acetaldehyde resin, 489-497
- , — enzymes as catalysts in, 490
  - , — modified, 492, 493
  - , — oxidation of, 492
  - , — properties of, 491-493
  - , — use, sound records, 1335
- Acetaldehyde-resorcinol resins, 278
- Acetaldol, production of, 489, 494, 497, 498
- , — resinification of, 490, 499
- Acetaldol-aniline product, rubber accelerator, 705
- , — from  $\beta$ -naphthol-acetaldehyde reaction, 283
- Acetalglycerol, reaction with phenol alcohols, 333
- Acetal reaction, time of, 496
- Acetals, action of alcoholic potash on, 495
- , — condensation of, 55
  - , — diluents in polymerization of 1,3-dienes, 182, 183
  - , — from acetylene, 495
  - , — reaction with alkali, 495
  - , — vinyl compounds, 1064, 1065
  - , — resinification of, 495
  - , — unsaturated ethers from, 1007
- Acetamide, esterification of rosin with, 801
- , — modifier, urea-aldehyde resins, 684
  - , — reaction with copal, 810
  - , — formaldehyde, 573, 592
- 4-Acetamidodiphenyl selenide dihydroxide, 1241
- Acetanilide, catalyst, phenol-formaldehyde reaction, 845
- , — plasticiser, alkyl resins, 882, 890
  - , — phenol-aldehyde resins, 388, 429, 440
- Acetates, catalysts, for phenol-alcohol resins, 332
- , — from ketene and tertiary alcohols, 554
- Acetate silk, printing with modified phenol-aldehyde resin, 442
- , — printing with urea resins, 641
- Acetic acid, action on indene, 102
- , — methylolurea, 578, 592
  - , — pine oil, 781
  - , — activator, hydrogenation of esters, 807
  - , — catalyst, catechol-acetone resin, 387
  - , — condensation of 3,3,4,4-tetraphenylcyclobutane-1,2-dione, 453
  - , —, — dicyanodiamide-formaldehyde reaction, 679
  - , —, — formaldehyde-alkyl salicylate reaction, 374
  - , —, — hydrocarbon-formaldehyde reaction, 264
  - , —, — phenol-acetone reaction, 388
  - , —, — phenol-aldehyde reaction, 843, 849, 429, 430
  - , —, — polymerisation of butadienes, 175
- Acetic acid, catalyst, polymerization of methyleneurethane, 682
- , —, — resin formation, 278
  - , —, — thiourea and formaldehyde, 658
  - , —, — urea-acrocin reaction, 670, 671
  - , —, — urea resins, 595, 599, 617, 640, 656
  - , —, — compound with methyleneurea, 578, 579
  - , —, — condensing agent, amines and aldehydes, 707, 708
  - , —, — urea and acetaldehyde, 642
  - , —, — decomposition, thermal, 552
  - , —, — dehydrating agent, urea-formaldehyde resins, 600
  - , —, — depolymerization of polystyrene with, 234
  - , —, — diluent for cresol, 280
  - , —, — effect of, phenol-aldehyde molding composition, 321, 322
  - , —, — esterifying agent, for montan wax alcohols, 814, 815
  - , —, — fluxing agent, urea resins, 598
  - , —, — from pinene, 783
  - , —, — from rubber oxidation, 1093
  - , —, — hardening catalyst, polyvinyl esters, 1029
  - , —, — in phenol-sulphur resins, 1186
  - , —, — neutralizing agent, saligenin preparation, 281
  - , —, — polymerization of styrene with, 234
  - , —, — precipitant for chlororubber, 1126
  - , —, — precipitating bath for alkyl resin thread, 989
  - , —, — production, 496, 497
  - , —, — purification of resins with, 336, 467
  - , —, — reaction with acetylene, 161, 1017
  - , —, — carbon suboxide, 1012
  - , —, — dibenzoylperoxide, 556
  - , —, — pentaerythritol, 901
  - , —, — sulphur trioxide, 1018
  - , —, — vinyl acetate, 1032
  - , —, — vinylacetylene, 151
  - , —, — resistance of cumarone resin to, 130
  - , —, — solvent, acetaldehyde-phenol resin, 283
  - , —, — benzaldehyde-phenol resin, 278
  - , —, — cellulose esters, 39
  - , —, — methyl acrylate polymers, 1072
  - , —, — modified phenol-aldehyde resin, 441
  - , —, — polyvinyl acetate, 1025
  - , —, — treatment of lithopone with, 978
  - , —, — use of, in alkyl resins, 905

 —, incorporation with urea resins, 608  
 Aniline hydrochloride, action of sulphur chloride on, 1193  
 —, catalyst, phenol-carbohydrate resins, 759  
 —, —, phenol-furfural reaction, 527  
 —, —, phenols with unsaturated aldehydes, 393  
 —, —, hardening agent, thiourea resins, 654  
 —, —, hardening agent, urea-phenol-aldehyde resins, 674  
 —, —, incorporation with phenol-rubber product, 1104  
 —, —, purification of phenol-aldehyde resin with, 337, 338  
 —, —, reaction with tung oil, 1270  
 Aniline hydrochloride-furfural, resin from, 534  
 p-Aniline-N-methylsulphonamide, 716  
 Aniline-modified phenol-aldehyde resin, use in dyeing, 425, 426  
 Aniline-stearic acid-furfural resin, 425  
 Aniline-sulphonamides, reaction with aldehydes, 715, 716  
 Aniline-sulphur resins, see Sulphur-aniline resins  
 Animal charcoal, catalyst, condensation of urea and formaldehyde, 593, 694

- Animal fibers, deterioration, effect of urea resins, 640  
 —, protection against alkali, 1191  
 Animal glue, modifier, phenol-formaldehyde resins, 416, 417  
 Animal oils, use in urea-resin lacquers, 636  
 Anisalacetone, resinifications, 562  
 Anisalcinnamylidenacetone, resinification, 562  
 Anisaldazine, pyrolysis, resin formation, 735  
 Anisaldehyde, condensation with tri-*p*-aminophenylacetonitrile, 733  
 —, from *p*-propenylanisole, 725  
 —, reaction with dehydrocholic acid, 509  
 —, resinification of, 569  
 Anise, oil of, resinification, 1253  
 Anisic acid, from, *p*-propenylanisole, 725  
 Anisole, aralkyl halides from, 1132  
 —, condensation with methylal, 343  
 —, fluorinated, 1157  
 —, modifier, phenol-aldehyde resins, 431  
 —, plasticiser, polyvinyl chloride, 1038  
 —, reaction with formaldehyde, 265, 407  
 —, reaction with ketene, 554  
 —, resinous material from, 271  
 —, solvent, alkyd resins, 880  
 —, solvent, polyvinyl acetate, 1025  
 Anisyl alcohol esters, modifiers, phenol-aldehyde resins, 431  
 3-*p*-Anisylindazole, resinification, 736  
*p*-Anisyl ketones, autocondensation of, 555  
 Annealing treatment, of polystyrene moldings, 249  
 Anisole-acids, 194  
 Antacids, use with chlorinated rubber, 1111, 1112  
 Anthracene, air-oxidation, 883  
 —, as plasticiser, 940  
 —, autocondensation of, 266  
 —, chlorinated, condensation with formaldehyde, 266  
 —, chlorination of, 1137  
 —, condensation products from, in tanning agents, 267  
 —, condensation with aromatic hydrocarbons, 266  
 —, condensation with olefins, 194  
 —, decomposition products of, 268  
 —, diene reactions of, 833, 839, 840  
 —, dye for polystyrene, 237  
 —, effect on polymerization of styrene, 239  
 —, from benzyl chloride, 1131  
 —, in fluorescent paint, 1091  
 —, inhibitor, polymerisation of styrene, 242  
 —, phthalic anhydride from, 833  
 —, reaction with maleic anhydride, 839  
 —, —, sulphur, 1202  
 —, softening agent, phenol-aldehyde resins, 423, 440  
 —, structure of, 839, 840  
 Anthracene derivatives, from acetylene polymerization, 144  
 Anthracene-formaldehyde resins, 264  
 Anthracene oil, condensation products in tanning agents, 267  
 —, drying oil substitute from, 1008  
 —, from coal-tar pitch, 274  
 —, reaction with aromatic sulphonyl chlorides, 722  
 —, resin from, 269  
 —, solvent in cold-molding compositions, 1235  
 Anthracene refining residues, treatment with sulphur, 1204  
 Anthracene resin, from benzene and vinyl chloride, 1045  
 Anthracene-type resin, 256  
 Anthranilic acid, use in amine-aldehyde condensations, 696  
 Anthraphenone, halogenated, 1157  
 Anthraquinoid dyes, with phenol-aldehyde resins, 442  
 —, with urea-aldehyde-ammonia resins, 684  
 Anthraquinone, preparation of, 834  
 9-Anthryl dithiochloride, resin from, 1202  
 Anti-agers, from acrolein, 865  
 —, in synthetic rubbers, 197, 198  
 Anti-aging effect in ester gum varnishes, 821  
 Anti-coagulant, rosin as, 775  
 Anti-corrosive paint, from vulcanised products, 1203  
 Anti-foaming agents, 353  
 Anti-fouling coatings, sulphur in, 1161  
 Anti-fouling paint, cumarone resin in, 129  
 —, ester gum in, 820  
 —, from phenol resin, 451  
 Anti-halation layers, 375, 384  
 Anti-knock agents, 791  
 Antimony chloride, acetone solvent, 1219  
 —, action on rubber, 1102  
 —, catalyst, chlorination of naphthalene, 1151  
 —, chlorination of biphenyl, 1142, 1143  
 —, polymerized tung oil with, 1219  
 Antimony compounds, catalysts, phenol sulphur resins, 1191  
 Antimony halides, catalysts, polymerisation of, 1,3-dienes, 175, 183  
 Antimony hydroxide, catalyst, acetaldol formation, 498  
 Antimony oxide, in mixed-pigment paints, 977  
 Antimony pentachloride, action on dundene, 105  
 —, action on indene, 102, 103  
 —, catalyst, cumarone polymerization, 117  
 —, —, naphthalene resins, 1136  
 —, —, polycyclopentadiene formation, 187  
 —, —, polymerization of dimeric 2,3-dimethylbutadiene, 172  
 —, —, polymerisation of vinyl ethers, 1010  
 —, oxidation catalyst, for fatty oils, 1225  
 —, polymerisation catalyst, 50  
 Antimony trichloride, action on indene, 102  
 —, incorporation with sulphur, 1163  
 —, overcoming stickiness of rubber with, 1095  
 —, use, fireproofing fibers, 418  
 Antioxidants, aniline-modified phenol-acetaldehyde resin, 424  
 —, classification, 708  
 —, effect in styrene polymerisation, 241  
 —, effect on chloroprene polymerization, 156, 157, 173  
 —, effect on durability of spar varnish, 1368  
 —, from naphthenates, 207  
 —, in ester gum varnish films, 821  
 —, rubber, 709, 732  
 —, use in diolefin-monoolefin co-polymerisation, 193  
 Antiparallelic adhesive layers, use of polystyrene in, 245  
 Antipyrine, resin from, 574  
 Anti-rust paint, from, polyvinyl esters, 1026  
 Antiseptic coatings, sulphur in, 1161  
 Antiseptic fibers, preparation, 415  
 Antiseptics, from dichlorophenol derivatives, 1154  
 —, from phenols, 277  
 —, from pine oil, 783  
 —, from salicylic and gallic acids by condensation, 277  
 Aporphine alkaloids, resins from, 745  
 Apparatus, for natural resin esterifications, 811-813  
 —, for polymerisation of 1,3-dienes, 177, 179  
 Aqueous coating composition, 832  
 Aqueous dispersion, ester gum, 824  
 —, rubber, 1091  
 Aqueous emulsions, as coating compositions, 662  
 —, cellulose esters, 824  
 —, compounding of rubber, 435  
 —, of resins, uses, 1334  
 —, preparation of molding compositions, 441  
 Aqueous paints, use of alkyd resin emulsions in, 948  
 Arachidic acid, 787  
 Aralkyl halide-phenol condensations, 1133  
 Aralkyl-halide resins, coatings, 1130  
 Aralkyl halides, preparation, 1132  
 Aralkyl halides and hydrocarbons, 1131  
 Arbor press, use, 1331  
 Arc-extinguishing agent, ammonia as, 566  
 Arcing characteristics, in laminated materials, 1347  
 Arc-lamp irradiation, varnish tests by, 1368  
 Arc light, effect on furfural-aniline reaction, 536  
 Arc-resistant materials, alkyd resin coatings for, 926  
 Arginine, from wool hydrolysis, 63  
 —, reaction with benzenesulphonylchloride, 722  
 Aridyne, as drier standard, 786  
 Aroclor-ester gum coatings, 830, 821

- Aroclors, adhesives for metal and glass, 1150

- Asbestos**, use, with chlororubber, 1126  
 —, —, with phenol resin coatings, 449, 450  
**Asbestos-alkyd resin composition**, 964  
**Asbestos cloth**, alkyd resin binder for, 987  
**Asbestos composition**, alkyd resin coating for, 964  
**Asbestos fabric**, molded products, 1273  
**Asbestos fibers**, use of polystyrene solutions with, 245  
**Asbestos-filled molding composition**, preparation, 1273  
**Asbestos-paper mixture**, filler, 1250  
**Asbestos pulp**, filler, 329  
**Asbestos sheets**, impregnation with phenol resin, 474, 482  
**Asbestos yarn**, impregnation with phenol resin, 472  
**Ash content**, coal-tar pitch coke, 360  
 —, cumarone resin, 111  
 —, sludge paracumarone, 113  
**Ashes**, use, finishing moldings, 1331  
**Asparagane**, condensation with formaldehyde, 699  
**Asphalt**, artificial, containing rosin, 778  
 —, asphaltenes from, 205  
 —, binder for cold-molding compositions, 1285  
 —, chlorobiphenyls in, 1147  
 —, definition of, 12  
 —, from acid sludge, 217  
 —, from hydrocarbons and sulphur, 215, 216  
 —, incorporation with rubber, 1091  
 —, ingredient of anti-corrosive paint, 1203  
 —, in tar-oil resin varnishes, 122  
 —, molding of, 1314, 1315, 1316, 1317  
 —, petroleum, action of aluminum chloride on, 274  
 —, plasticity of, 34  
 —, reaction with sulphuric acid, 1203  
 —, treatment with acid sludge, 218  
 —, treatment with sulphur, 1203  
 —, use, molded insulation material, 986  
 —, —, mold-lubricant, 1328  
 —, —, with cellulose esters, 1243  
 —, —, with chlororubber, 1119, 1126  
 —, —, with tung oil, 1218  
 —, vulcanized, uses for, 1203  
 —, with cumarone resin, 138  
 —, with phenolic resin, binder, 482, 483  
**Asphalt-alkyd resin varnish**, 978  
**Asphalt-chloronaphthalene compositions** in insulation, 1152  
**Asphaltenes**, by oxidation of petroleum, 204  
 —, from petroleum, 201, 202, 203, 204  
 —, from sulphur compounds, 204, 205  
 —, hydrogenation of, 205  
 —, oxidation of petroleum, 208, 209  
 —, properties of, 204  
 —, reaction with perbenzoic acid, 203  
**Asphalt-felt base**, for floor coverings, 984  
**Asphaltic acids**, from petroleum, 205  
 —, oxidation of bitumen, 210  
**Asphaltic bitumen**, definition of, 12  
**Asphaltic compounds**, moldings, 454  
**Asphaltic materials** from peat, 749  
**Asphaltic resins**, oxidation of petroleum, 208, 209  
**Asphalt moldings**, coating, 1334  
**Asphaltogenic acids**, from petroleum, 203, 208  
**Asphalt-pitch mixture**, modifier, phenol-aldehyde resins, 426  
**Asphaltum**, chlorinated, in varnishes and paints, 1155  
 —, use of, with phenol-aldehyde resins, 287, 332  
**Asphalt varnishes**, for artificial leather, 965  
 —, protective coatings from, 1377  
**Association colloids**, nature of, 72, 73  
**Athermal plasticity**, 31, 32  
**Atmosphere**, inert, in preparation of alkyds, 922, 923, 931  
 —, inert, in "sodium" polymerization of 1,3-dienes, 182  
**Atropic acid**, polymerization, 1084  
**Aurin**, absorption spectra of, from Bakelite, 312  
 —, from condensation of phenol and formaldehyde, 294  
**Autocatalysis**, nature of, 45  
**Autoclave**, manufacture of urea in, 566, 567, 569  
 —, use of, 239, 331, 340, 1110, 1111  
**Autocondensation**, of acetaldehyde, 499  
 —, of anthracene, 266  
**Autocondensation**,  $\omega$ -hydroxypentadecanoic acid, 872  
 —, of phenanthrene, 266  
**Automatic machinery**, cost of, 1321  
**Automatic presses**, 1312  
**Oxidation**, in polymerization of 1,3-dienes, 176  
 —, of cumarone, 95  
 —, of rosin, 775  
 —, of styrene, 240  
**Awning cloth**, from chloroprene rubber, 159  
**Azelaic acid**, use in alkyd resins, 883, 892, 908  
**Azelaic anhydride**, rate of reaction with water, 996  
**Azine dyes**, use, sound records, 1336  
**Azines**, thermal decomposition, 735  
**Azo-dyes**, colored phenol-resin varnishes with, 453  
 —, coloring sulphur with, 1161  
 —, for polystyrene, 237  
 —, incorporation with, urea resin, 648  
**Azo-group**, in resins, 734  
**Azomethane grouping**, in polydimethyleneurea, 580  
**Azomethines**, structure, 688  
**Azulmic acid**, 731

## B

- Baeyer reaction**, 294  
**Baked coatings**, alkyds resins, asbestos in, 964  
 —, from tung oil, 1216, 1217  
**Baked-on alkyd enamels**, in finishing operations, 961  
**Bakelite A**, structure of, 58  
 —, as adhesive, 1004  
**Bakelite C**, similarity to graphite, 303  
 —, structure of, 59, 60, 302, 303  
**Bakelite**, as insulator, 432  
 —, chemical resistance of, 454  
 —, compared with urea resin moldings, 565  
 —, compatibility with chlororubber, 1119  
 —, constitution of, 299  
 —, hardening of, influence of electrical field, 312  
 —, hardening process, 318  
 —, production of, 316, 317, 318  
 —, three-stage preparation, 454  
 —, uses of, 314  
**Bakelite lacquers**, blending with urea resin lacquers, 634  
**Bakelite moldings**, cumarone resin in, 134  
**Bakelite paint**, testing of, 1368  
**Bakelite substitute**, phenol-sulphur resins, 1190  
**Bakelizer**, conversion of resins in, 454  
 —, description of, 286  
 —, uses of, 365  
**Baking**, conversion of phenol resins by, 443  
 —, of alkydal resins, 957  
 —, of alkyd resins, 960  
 —, of chlororubber films, 1122  
 —, of cold moldings, 1291, 1317  
 —, of Glyptal films, 961  
 —, of molded products, from phenol-formalin resins, 318  
 —, of phenolic material, effect on power factor, 1349  
 —, of phenolic resin moldings, 463  
 —, of phenol resin coatings on wood, 450, 451  
 —, of synthetic-resin varnish, 1250  
 —, of urea resin films, 633  
 —, polymerization of crotyl cellulose by, 1081  
**Baking-varnishes**, by esterification of copal-rosin oil mixtures, 811  
 —, time of drying, 1364  
**Balance weights**, from resins, 1267  
**Balata**, chain length of, 75  
 —, co-polymerization with diolefins, 200  
 —, distillation of, 1092  
 —, hydrogenated, properties of, 1096  
 —, in insulating compositions, 1098, 1091, 1152  
 —, molecular weight of, 53, 75  
 —, oxidation of, 775  
 —, reaction with halogens, 1105, 1108, 1113, 1115  
 —, specific viscosity of, 75  
 —, structure of, 52  
**Balata hydrocarbons**, absorption of oxygen by, 1093  
**Balata-like polymers**, from butadiene derivatives, 173

- Balata resin, adhesive from, 1100  
 —, hardening of, 1102  
 —, reaction with aldehydes, 777  
 Balata substitutes, as adhesives, 1100  
 —, from rubber, 1099  
 Ball bearings, use of resins in, 1248  
 Ball mill, uses of, 337, 358, 455, 1278  
 Balloon fabrics, coated with modified chlororubber, 1124  
 Balloon varnish, from vulcanised oils, 1208  
 Ball-shaped preforms, uses of, 1319, 1321, 1332  
 Balsam, preparation of, 968  
 —, prevention of blushing with, 968  
 —, properties of, 12  
 —, synthetic, from wood tar, 752  
 Balsam-like substances, by polymerization of terpenes, 106  
 Banana juice, as protective colloid, 181  
 Banbury mixer, uses of, 138, 1279  
 Bandage impregnant, from rubber, 1092  
 Bands, extrusion of, 1323  
 Bangor nut oil, coatings for metals from, 1232, 1233  
 Barbituric acid derivatives, formation of, 571  
 Barium carbonate, catalyst, solidification of alkylid resins, 980  
 —, resins from wood neutralised with, 748  
 —, use in phenol-formaldehyde condensation, 350  
 Barium chloride, catalyst, preparation of vinyl chloride, 1035  
 —, reaction with chloropropionyl chloride, 1074  
 —, — polymethacrylic acid, 1080  
 Barium cyanide, catalyst, acetylene-hydrogen cyanide reaction, 1070  
 Barium ethylsulphate, catalyst, hardening urea resins, 618  
 Barium hydroxide, catalyst, acrolein polymerization, 502  
 —, —, aldol formation, 498, 499  
 —, —, phenol-alcohol resins, 332  
 —, —, preparation of acetaldehyde resin, 490  
 —, —, solidification of alkylid resins, 980  
 —, —, condensing agent, acetone and formaldehyde, 547  
 —, —, formaldehyde and acetaldehyde, 546  
 —, —,  $\beta$ -naphthoquinone and oxygen, 558  
 —, —, oxygen and carvone, 558  
 —, —, oxygen and p-benzoquinone, 553  
 —, —, oxygen and phenanthrenequinone, 553  
 —, —, oxygen and piperitone, 558  
 —, —, oxygen and pulegone, 558  
 —, —, thiourea and formaldehyde, 653  
 —, —, urea and formaldehyde, 592, 615  
 —, —, modifier, phenol-aldehyde resins, 438  
 —, —, precipitation of resins by, 695  
 —, —, reaction with cinnamalacetic acid, 1083  
 —, —, resin purification with, 337  
 —, —, solvent, for phenol-aldehyde resins, 319  
 —, —, styrene from cinnamic acid with, 255  
 Barium lactate, crystallization of, 1003  
 —, reaction with water, 1003  
 Barium monocetyl phthalate, properties of, 984  
 Barium naphthoates, uses, 206  
 Barium oleate, modifier, phenol-aldehyde resins, 400  
 Barium oxide, action on quinoline, 739  
 —, catalyst, cumarone polymerization, 117, 119  
 —, resin purification with, 337  
 —, rosin esterification with, 794  
 —, rosin hardened with, 772  
 —, use, with chlororubber, 1111  
 Barium peroxide, catalyst, heteropolymerization, vinyl chloride and maleic anhydride, 1044  
 —, —, polymerization of vinyl chloride, 1038  
 —, —, vinyl-ester polymerization, 1057  
 Barium peroxide-acetic anhydride mixture, catalyst, polymerization of 1,3-dienes, 183  
 Barium resinate, modifier, phenol-aldehyde resins, 400  
 Barium salts, of alkylid resins, 946, 949  
 Barium soaps, modifiers, phenol-aldehyde resins, 438  
 Barium sulphate, filler, chloronaphthalene compositions, 1188  
 —, —, molding compositions, 1275  
 Barium sulphate, filler, phenol-aldehyde resins, 317, 318, 477  
 —, —, sulphone-amide resins, 719  
 —, —, synthetic resins, 1251  
 —, —, gelatinous, preparation of, 30  
 Barium thiosulphate, for decorating molded products, 484  
 Barium titanate, pigment for alkylid resin paints, 977  
 Baryta, use in floor covering, 964  
 Baryta water, catalyst, phenol-formaldehyde reaction, 343  
 —, —, saligenin preparation, 281  
 Barytes, effect of, in synthetic rubber, 196  
 —, filler, chlororubber cement, 1126  
 —, —, sound records, 1236  
 Bases, flocculants, methyloleures, 595  
 —, organic, effect on rubber hydrochloride, 1112  
 —, —, treatment of sulphonated resins, 426  
 —, —, use in polymerization of diolefins, 182  
 —, removal from coal-tar naphtha, 107, 108, 214, 116  
 —, solvents for vulcanisation accelerators, 196  
 Basic catalysts, for aniline-formaldehyde resins, 695  
 —, —, for phenol-aldehyde resins, 342, 344-348  
 —, —, for phenol-furfural condensation, 523  
 —, —, for phenol-sulphur resins, 1190, 1191  
 —, —, retardation of solidification, urea resins, 617  
 Basic dyes, phenol-sulphur resin mordant for, 1190  
 Basic pigments, with alkylid resins, 973  
 —, with ester gum, 818  
 Basic salts, condensing agents, urea and acrolein, 670  
 —, —, urea and formaldehyde, 616  
 —, —, for emulsification of diolefins, 180  
 Baskets, rubber composition, for centrifugal apparatus, 1248  
 Batavian dammar, resins from, 804  
 Battery boxes, from resins, 1267  
 Battery jars, from rubber-phenol-aldehyde composition, 434  
 Batu gum, in shellac substitutes, 778  
 Bauxite, catalyst, polymerization, 226, 227  
 Beadings, extrusion of, 1323  
 Bean proteins, modifiers, phenol-formaldehyde resins, 414, 416  
 Beef tallow, in modified alkylid resins, 936  
 Beeswax, constituent of shellac substitute, 1188  
 —, effect on chlororubber oil varnish, 1124  
 —, emulsifying agent, resorcinol-formaldehyde resin, 372  
 —, modifier, phenol-aldehyde resins, 411, 426  
 —, plasticity of, 34  
 —, use, in modified alkylid resins, 936  
 Beeswax acid, acylation of phenol-aldehyde resins, 426  
 Beetle, urea resin molding composition, 565, 627, 628  
 Belt dressing compound, rosin in, 778  
 Belting, from rubber isomers, 1100  
 Bentonite, addition to sulphur castings, 1166  
 —, use, in alkylid resin emulsification, 946  
 —, —, in dispersing ester gum, 824  
 Benzalazine, reaction with carbon disulphide, 1197  
 Benzalazine, reaction with maleic anhydride, 854  
 Benzal bromide, action on rosin, 1134  
 Benzal chloride, condensation with aniline, 1134  
 —, —, anthracene, 1134  
 —, —, naphthalene, 1134  
 —, —, phenanthrene, 1134  
 —, resins from, 1129, 1134  
 —, rosin esterification with, 799  
 Benzaldehyde, pyrolysis, resin formation, 735  
 Benzaldehyde, as homogenising agent, 970  
 —, condensation with solvent naphtha, 265  
 —, —, xylene, 265  
 —, effect of light on, 508  
 —, effect of ultraviolet rays on, 494  
 —, from polystyrenes, 239  
 —, polymerization of, 507, 508  
 —, reaction with acetic anhydride, 508  
 —, —, aliphatic amines, 688, 705  
 —, —, aliphatic ketone, 561  
 —, —, ammonium sulphide, 682

- Benzidine, condensation with lignin, 748  
 —, — terephthalaldehyde, 688  
 —, glyceride oils modified with, 1227  
 —, in rubber laminated stocks, 1099  
 —, softening agent, phenol-aldehyde resins, 424  
 —, use in alkyd resins, 922  
 —, — phenol-aldehyde resins, 347  
 Benzidine-acetone, as hardening agent, 392, 759  
 Benzidine-aldehyde resins, fluidity, 695  
 Benzidine-furfural resins, light-sensitive material from, 589  
 Benzil, resinification of, 509  
 Benzoic acid, thermal decomposition of, 1003  
 —, lactide from, 1003  
 Benzine, as varnish thinner, 817  
 —, precipitant, petroleum resins, 202  
 —, solvent, protein-modified phenol-aldehyde resins, 416  
 Benzozate, of hydroxyethyl vinyl ether, 1010  
 Benzofuran, *see* Cumarone  
 Benzoic acid, catalyst, amine-aldehyde condensations, 702  
 —, —, darkening of resins, 1244  
 —, condensing agent, urea and formaldehyde, 610  
 —, effect on coating films, 976  
 —, in cement for glass, 479  
 —, modifier, for oxidized fatty acids, 1227  
 —, —, for phenol-aldehyde resins, 424  
 —, phenol-aldehyde resins fused with, 398  
 —, polymerizing agent, methylolureas, 595  
 —, reaction with diversine, 745  
 —, scorch retarder for rubber, 985  
 —, softening agent for nitrocellulose films, 970  
 —, use in alkyd resins, 907, 935, 938, 942, 984  
 —, use in Teglaes, 914  
 Benzoic acid derivatives, as driers, 786  
 Benzoic anhydride, modifier, phenol-aldehyde resins, 439  
 —, use with phenol-aldehyde resins, 328  
 Benzoic esters, of phenol-aldehyde resins, 422  
 Benzoic-glycerol ester, composition with cellulose esters, 971  
 Benzoic-phthalic-glyceride resin in flooring compositions, 884  
 —, in nitrocellulose lacquer, 966  
 o-Benzoin sulphonamide, from toluene o-sulphonamide, 712, 713  
 —, saccharin from, 712, 713  
 Benzoin, arylalkyl substituted, metallic salts of, 953  
 —, condensation products as wetting agents, 268  
 —, nitration of, 725  
 —,  $\alpha$ -resin of, 1233  
 —, resinification of, 510  
 Benzoinolisin, polymerization, 738  
 Benzol, crude, cumarone resin from, 107, 115, 116  
 —, —, purification with maleic anhydride, 836  
 —, solvent, in cold-molding compositions, 1285  
 —, —, for ester gum paints, 820  
 —, —, for polyacenaphthalene, 260  
 Benzophenone, chlorine derivatives of, 1154  
 —, melts of, 29, 30  
 —, reaction with sodium vinylacetylide, 151  
 Benzophenone-dicarboxylic acid, condensation with m-cresol, 375  
 —, — ethylene glycol, 895  
 —, — glycerol, 893, 894, 895  
 —, in alkyd resins, 915, 924, 925, 930  
 Benzophenoneketazine, pyrolysis, resin formation, 735  
 Benzopyrylium salts, as condensing agents, 295  
 Benzoquinone, condensation with p-cresol methyl ether, 894  
 —, polymerisation inhibitor, 242  
 —, reaction with anthracene, 840  
 —, — butadiene hydrocarbons, 832, 833  
 —, — cyclopentadiene, 837  
 —, — isoprene, 830  
 —, — oxygen, 838  
 —, — phenylhydrazine, 561  
 Benzouocinin, preparation, 886  
 Benzothiazoles, condensation with aldehydes, 392  
 —, — ketones, 392  
 Benzotrithloride, in rubber accelerators, 707  
 —, reaction with aniline, 1135  
 —, — benzene, 1135  
 —, — cresol, 1135  
 —, — phenol, 1135  
 —, resinification of, 1129, 1135, 1136  
 Benzotrithloride-phenol-formaldehyde product, cold-molding composition, 1289  
 Benzoxazole guanidine derivative, preparation of, 572  
 Benzoylacetone, condensation with anisaldehyde, 563  
 —, — methylolbenzamide, 574  
 —, — m-nitrobenzaldehyde, 563  
 4-Benzoylaminoethyl-1,5-dimethyl-2-phenyl pyrazolone, from antipyrine, 574  
 Benzoylation, of polyvinyl alcohol, 1055  
 Benzoylbenzoic acid, condensation with glycerol, 894  
 —, — phenols, 376, 433  
 —, use in alkyd resins, 914  
 Benzoylbenzoic acid-phenol resins, reaction with aldehydes, 376  
 Benzoylcarbinol, catalyst, vinyl-acetate hydrolysis, 1056  
 Benzoyl chloride, action on alkylfurylcarbinols, 520  
 —, — phenol-sulphur resin, 1193  
 —, — rubber, 1100  
 —, reaction with  $\beta$ -3-dihydroindolylpropionic acid, 743  
 —, — diphenylbutadiene, 1138  
 —, — magnesylpyrrole and sulphur, 742  
 —, — 7-methylindole, 743  
 —, — silver isatin, 744  
 —, — sodium cresotate, 1254  
 —, — trioxymethylene, 516  
 Benzoyl cyanide, condensation with resorcinol, 378, 737  
 Benzoyl cystine, gels from, 38  
 $\omega$ -Benzoyl fatty acid, preparation of, 998  
 Benzoyl hydrogen peroxide, catalyst, polymerization of styrene, 240  
 $\alpha$ -Benzoylmethyl- $\gamma$ -butyrolactone, from 2-methyl-6-phenylcinchomeronic acid, 738  
 Benzoyl peroxide, action on rubber, 1093, 1094, 1109  
 —, as a polymerization catalyst, 49, 50  
 —, catalyst, condensation of maleic anhydride and vinyl acetate, 1034  
 —, —, condensation of vinyl acetate and trichloroethylene, 1034  
 —, —, polymerization of aldehydes, 505  
 —, —, — diolefins, 175, 180  
 —, —, — esters of unsaturated acids, 1076, 1071  
 —, —, — furethylene, 243, 522  
 —, —, — hydrogenated divinylacetylene, 154  
 —, —, — styrene, 176, 240, 243  
 —, —, — vinylacetylene, 150  
 —, —, — vinyl chloride, 1038, 1040  
 —, —, — vinyl esters, 1024, 1034, 1045, 1046, 1057, 1067  
 —, —, — vinyl ethinyl carbinols, 151  
 —, —, — vinyl ester-aldehyde reaction, 1065  
 —, reaction with pyridine, 737  
 Benzoyl yeast-gum, depolymerization, 763  
 Benzuramidobutyric esters, formation of, 576  
 Benzuramidocrotonic ester, resins from, 576  
 Benzyl abietate, formation, 797  
 —, in smokeless powder, 824  
 Benzyl acetate, copal esterified with, 810  
 —, modifier, for phenol-aldehyde resin, 399, 400  
 —, reaction with phthaloyl chloride, 1254  
 —, rosin esterification with, 801  
 —, solvent, alkyd resins, 880  
 —, use in alkyd resin production, 925  
 Benzyl alcohol, catalyst, vinyl-acetate hydrolysis, 1056  
 —, dehydrating agent, urea-formaldehyde resins, 600, 601  
 —, dehydration of, 146, 267  
 —, esterification of aralkyl halide resins, 1132  
 —, reaction with glycerol and urea, 664  
 —, — phenol, 295  
 —, — rosin, 799  
 —, — sulphuric acid trihydrate, 267  
 —, resins from, 267, 1007  
 —, softening agent, urea-formaldehyde resin, 604  
 —, solvent, alkyd resins, 880

- Benzyl alcohol, solvent, benzoyl chloride-cresotic acid resins, 1254  
 —, —, urea-formaldehyde condensation, 637  
 —, —, urea-phenol-aldehyde resin, 676  
 —, use, in alkyd resins, 925, 936  
 —, —, in castor oil-maleic compositions, 909  
 Benzyl alcohol disulphide, 1184  
 Benzylamine, catalyst, in phenol-aldehyde condensation, 363, 365  
 $\alpha$ -Benzyl- $\beta$ -aminopropionic acid, preparation, 688  
 —, condensation with benzylmalonic acid half aldehyde, 688  
 Benzylamylonic esters, 762  
 Benzylaniline, condensation with formaldehyde, 699  
 Benzylanthracene, bromination of, 1156, 1157  
 Benzylated starch derivatives, 762  
 Benzyl benzenesulphonate, decomposition of, 1206  
 Benzyl benzoate, solvent, benzoyl chloride-cresolic resins, 1254  
 —, —, alkyd resins, 879  
 —, use, in alkyd resin production, 925  
 Benzyl bromide, reaction with zinc-copper couple, 1130  
 Benzylbromoacetaldehyde, polymerization of, 506  
 Benzylcellulose, coating composition from, 447  
 —, in flooring composition, 824, 1150  
 —, polyalkylene oxide plasticizer for, 993  
 —, use with glycerol esters, 969  
 —, —, synthetic resins, 1244  
 Benzyl chloride, as hardening agent, 1132  
 —, as solubilizing agent, 1132  
 —, catalyst, phenol-aldehyde reaction, 357, 352  
 —, condensation with aluminum chloride, 55  
 —, —, benzene, 1131  
 —, —, casein, 1133  
 —, —, methylnaphthalene, 1131  
 —, —, naphthalene sulphonic acid, 1132  
 —, —,  $\alpha$ -naphthol, 1133  
 —, —, nitrobenzaldehydes, 509  
 —, —, phenol, 295  
 —, —, rubber, 1133  
 —, —, sodium indene, 98  
 —, —, trioxymethylene, 299  
 —, —, xylene, 1137  
 —, condensing agent for sugar resins, 759  
 —, plasticizer, polyvinyl chloride, 1038  
 —, resinification of, 1129, 1131  
 —, resin esters with, 799  
 —, reaction with metals, 1130, 1131  
 —, use in polymerization of diolefins, 183  
 Benzyl cinnamate, polymerization, 1032  
 Benzyl dihydro-anthraquinyl dipyridinium dibromide, hydrolysis of, 1157  
 p-Benzylidiphenylmethane, 1131  
 Benzyl ester, of abietic acid, in chewing gum, 828  
 —, —, in waterproofing agent for paper, 828  
 Benzyl ether, introfier for sulphur, 1165  
 —, of phenol-aldehyde resins, 422  
 Benzylglycol, action on urea resins, 659  
 Benzylideneacetophenone, reaction with resorcinol, 295  
 —, reaction with chloranil, 295  
 Benzylideneaniline, resinification, 710  
 N-Benzylideneglycylglycine, resinification of, 689  
 2-Benzylidene-3-phenyl- $\Delta^4$ - $\beta$ -naphthpyran, from 2-naphthol-1-aldehyde and dibenzylketone, 563  
 —, polymerization, 563  
 Benzylidenepyrvic acid, polymerization of, 509  
 Benzylidene rubber, properties of, 1100  
 Benzylimidazol, reaction with methyl iodide, 736  
 Benzylindene, from sodium indene, 98  
 —, substitute for linseed oil, 98  
 Benzylmalonic acid, half aldehyde, preparation, 688  
 —, —, condensation with  $\alpha$ -benzyl- $\beta$ -aminopropionic acid, 688  
 Benzyl mercaptan, reaction with aldehydes, 377  
 Benzylmethylthallene, plasticiser, chlororubber, 1123  
 Benzylmethylthallene-sulphonic acid, reaction with phenol-formaldehyde resin, 419  
 Benzylpyridinium halides, resinification, 733  
 Benzyl succinic acid, preparation of, 839  
 1-Benzyl-1,2,3,4-tetrahydro isoquinoline, condensation with formaldehyde, 745  
 Biaryls, halogenation of, 1142  
 Bibenzyl, from benzyl chloride, 1131  
 —, from toluene, 268  
 Bibliography, of synthetic resins, 15, 16, 17  
 Bicarbazoles, from carbazole, 744  
 Binder, aldehyde-amine resins as, 703  
 —, chloroprene rubber as, 159  
 —, cumarone resin as, 135, 137, 138  
 —, dammar gum as, 482  
 —, for mica, 982  
 —, for molded products, 1271  
 —, from molasses, 762  
 —, furfural-aniline resin as, 535  
 —, furl alcohol resins as, 522  
 —, modified phenol-aldehyde resins as, 417  
 —, phenol-aldehyde-oil resins as, 405, 407, 427  
 —, phenol-aldehyde resins as, 329, 452, 460, 461, 471, 472, 473, 474, 475, 476, 478, 484, 485  
 Binder, polyamides and polyesters as, 1000  
 —, oxidized rubber as, 1093  
 —, polyacrylic ester as, 1077  
 —, polymerized acrylic acid as, 1076  
 —, polymerized butadiene as, 183, 184  
 —, polystyrene as, 245, 251  
 —, rosin in, 777  
 —, rubber as, 482, 1095  
 —, sugar-formaldehyde resin as, 758  
 —, urea resin as, 624, 630  
 Binders, classification, 1271  
 —, loss of, with organic fillers, 462  
 —, oxidizing Rezyls as, 956  
 Binding agent, for abrasives, 1197  
 —, from gas-purification extract, 122  
 —, from waste liquors, 753  
 Biphenyl, action of cathode rays on, 269  
 —, chlorinated, in protective coatings, 1147  
 —, —, introfier for sulphur, 1147, 1165  
 —, —, resins from, 1150  
 —, —, use with alkyd resins, 943, 944  
 —, chlorination of, 1129, 1142, 1143, 1144, 1145  
 —, reaction with aldehydes, 263  
 —, synthesis of, 268, 1142  
 Bipiperidyl, catalyst, for acrylic acid chloride polymerization, 1075  
 Birch wood, plastic materials from, 749  
 Bismuth bisulphate, in varnish, prevention of yellowing, 1378  
 Bismuth chloride, action on rubber, 1102  
 —, catalyst, oxidation of phenol, 271  
 —, —, preparation of vinyl chloride, 1035  
 Bismuth halides, catalyst, polymerization of diolefins, 183, 187  
 Bismuth nitrate, in varnish, prevention of yellowing, 1378  
 Bitumen, definition of, 12  
 —, from Russian peat, 274  
 —, incorporation with chlororubber, 1119  
 —, —, rubber, 1092  
 —, oxidation of, 210  
 —, resinified with unsaturated hydrocarbons, 179, 229  
 —, uses of, 12, 360  
 Bituminous coal, chlorination of, 1156  
 —, varnish resin from, 275  
 Bituminous materials, in floor-covering, 199  
 —, moldings from, 1323, 1334  
 —, reaction with sulphur chloride and sulphur, 1203  
 —, vulcanized, 1203, 1204  
 Bituminous paint, cumarone resin in, 132  
 Biuret, alcoholization of, 571  
 —, adhesive from, 685  
 —, formation of, 570  
 —, reaction with formaldehyde, 685  
 —, urethan from, 571  
 Black liquor, from wood pulp, 753  
 Blanc fixe, filler in sound records, 1336  
 Bleach solutions, action on chlororubber paints, 1121  
 Bleaching, of alkyd resins, 908  
 —, of chlororubber solutions, 1124, 1125  
 —, of furfural resins, 535  
 —, of montan wax, 814  
 —, of phenol-aldehyde resins, 339  
 —, of rosin, 770, 776  
 —, of tanning compounds, 750

- Bleaching powder, action on cumarone, 94  
 —, effect on alkyl resins, 980  
 Blistering, of moldings, 607, 1315, 1320, 1328, 1329  
 —, of paraformaldehyde-cresylic acid resin, 365  
 —, urea resins, effect of cellulose, 620  
 Block printing color, from tar oils, 1203  
 Blood, dried, use with synthetic resins, 1250  
 Blood serum, modifier, phenol-formaldehyde resins, 414, 416, 417  
 Bloom oil, 779  
 Blooming, of cumarone resin, 1162  
 —, of films, nature of, 40  
 —, of rosin, 771  
 —, of varnish films, 127, 774  
 Blowing mold, use of, 1294  
 Blown oils, modifiers, for alkyl resins, 908, 932, 967  
 Blushing, of nitrocellulose films, 913, 968  
 —, of cumarone resin lacquers, 129  
 Bodied drying oils, use with alkyl resins, 929  
 Bodied tung oil, use with ester gum, 825  
 Body enamel, soya bean oil in, 974  
 Bonding strength, of laminated stock, 1352, 1353  
 Bone, filler, for phenol-aldehyde resins, 317, 318  
 Bone black, determination of, in resins, 1261  
 Bone oil, use of, 321, 322  
 Bone pitch, pigment, chlororubber paint, 1120  
 Bone substitutes, amine aldehyde resins as, 698  
 Bone-binding materials, from chloroprene rubber, 159  
 Borax, catalyst, for phenol-alcohol resin, 332  
 —, —, urea-formaldehyde reaction, 590  
 —, control of pH with, 353  
 —, effect, on polyvinyl alcohol, 1058  
 —, emulsifying agent, 372  
 —, in alkyl resin paints, 977  
 —, in urea resins, 645  
 —, rosin purification with, 767  
 Borax solution, solvent for casein, 415  
 Boric acid, bleaching resins with, 336, 467, 908  
 —, catalyst, curing cellulose-urea resin compositions, 622  
 —, —, esterification of rosin, 400, 796, 800  
 —, —, esterification of shellac, 813  
 —, —, phenol-acetone reaction, 389  
 —, —, phenol-formaldehyde reaction, 349  
 —, —, polymerization of tung oil, 401  
 —, —, ricinoleic acid condensation, 1224  
 —, —, urea-aldehyde reaction, 594, 631, 662  
 —, —, condensation of glycol by, 893  
 —, —, inhibitor, hydrolysis of rosin ester, 811  
 —, —, in rosin-oil production, 779  
 —, —, in rosin purification, 767  
 —, —, neutralizing agent, 405  
 —, —, reaction with polyvinyl compounds, 1057  
 —, —, refining oils with, 893  
 —, —, use, in alkyl resins, 881, 911, 937  
 —, —, use, in modified urea-aldehyde resin, 695  
 Boric anhydride, effect on cumarone polymerization, 107  
 Boric esters, refining oils with, 893  
 Boric oxide, catalyst, phenol-formaldehyde reaction, 349  
 Borneol, diterpenes from, 725  
 —, from linalool, 783  
 —, plasticizer, urea-formaldehyde resins, 601  
 —, reaction with aldehydes, 516, 525, 782  
 —, —, zinc chloride, 725  
 —, —, use with castor oil-maleic compositions, 909  
 —, —, alkyl resins, 903  
 Borneol-rosin esters, preparation, 800  
 Bornyl chloride, reaction with formaldehyde, 515, 516, 783  
 Boron compounds, catalysts, phenol-acetone reaction, 386  
 Boron fluoride, anisole acid from, 194  
 —, catalyst, acetylene-acetic acid reaction, 1017  
 —, —, for rosin esterification, 800  
 —, —, phenol-aldehyde reaction, 400  
 —, —, phenol-alkyl resin reaction, 917  
 —, —, phenol-fatty acid reaction, 1223  
 —, —, polymerization of cumarone, 109, 117, 119  
 —, —, polymerization of diolefins, 172, 175, 194  
 —, —, polymerization of olefins, 166, 185  
 —, —, polymerization of propylbenzene, 259  
 Boron fluoride, catalyst, polyvinyl ether formation, 1011  
 —, —, rosin-diisopropylcarbazole reaction, 805  
 —, —, precipitant, asphaltenes, 205, 215  
 Boron trichloride, action on indene, 102  
 —, catalyst, polymerization of diolefins, 183, 187  
 Boron triphenyl, reaction with amines, 1241  
 Bottle closures, from chlororubber, 1125  
 —, from phenol-furfural resins, 533  
 —, from urea resins, 627  
 Brake lining, from sulphurized linseed oil, 1209  
 —, synthetic resin in, 368, 459, 532, 649, 693, 732, 887  
 Brake material, sulphur containing, 1204  
 Bran, furfural from, 517  
 Breakdown voltage, for laminated materials, 1345, 1348  
 Breaking strength, of cold-molded phenol resins, 470  
 Brewers pitch, 778  
 Brinell hardness, determination of, 1351  
 Briquette binder, preparation, 121, 275, 729, 1203  
 Brittleness, of cumarone resin, 119, 134  
 —, of phenol-aldehyde resins, 372, 414, 415  
 —, of rosin varnish, 778  
 Bromalurea, formation of, 576  
 Brominated rubber, uses, 1125, 1126  
 Brominated triphenyl phosphate, uses, 718  
 Bromination, of benzylanthracene, 1156  
 —, of cumarone, 93  
 —, of divinylacetylenes, 152, 160, 161  
 —, of ethylbenzene, 253  
 —, of fatty acids, 1220  
 —, of indene, 97, 100  
 —, of phenols, 1154  
 —, of polyindene, 103, 104, 105  
 —, of polystyrene, 234, 237  
 —, of rubber, 1105, 1113, 1114, 1115  
 Bromine, action on films of acetylene polymers, 153  
 —, catalyst, phenol-aldehyde reaction, 393  
 —, —, phenol-ketone reaction, 388  
 —, —, rubber chlorination, 1110  
 —, inhibitor, rubber oxidation, 1128  
 —, purifying naphtha with, 116  
 —, reaction with acetylene, 143  
 —, —, cyclohexanonebenzil, 560  
 —, —, diversine, 745  
 —, —, isoprene sulphone, 171  
 —, —, phenol-aldehyde condensates, 312, 313  
 —, —, phenylisocyanylthiocarbamide, 658, 733  
 —, —, polyisobutylene, 166  
 —, —, polyvinyl alcohol, 1056  
 Bromine addition compound, of methyleneurea, 579  
 —, of urea resin, 580  
 Bromine addition product, of dimethyleneurea, 579  
 Bromine-chlorine mixture, rubber halogenated with, 1108  
 Bromine numbers, control of cooking oils by, 1226  
 Bromine water, effect of styrene polymerization, 241  
 Bromoacetal, condensation with *o*-toluidine, 782  
 Bromoacetaldehyde, from paraldehyde, 506  
 Bromoacetone, reaction with sodium sulphide, 1182  
 Bromoacetyl bromide, reaction with zinc, 552  
 $\beta$ -Bromoacrylic acid, from  $\beta$ -dibromopropionic acid, 1079  
 —, polymerization of, 1079, 1080  
 —, pyruvic acid from, 1080  
 Bromobenzene, alkylation of, 194  
 —, fluorinated, 1157  
 2-Bromo-1,3-butadiene, see Bromoprene.  
 $\beta$ -Bromobutyraldehyde, polymerization of, 506  
 Bromochloroethylene, polymerization, 1041, 1042  
 $\alpha$ -Bromocinnamaldehyde, phenylhydrazones, resinification of, 510  
 Bromocumarone, from cumarone dibromide, 93  
 1-Bromo-2,2'-dichlorodiethyl sulphide, decomposition, 1179  
 5-Bromo-3,4-dimethoxybenzaldehyde, polymerization of, 509  
 $\beta$ -Bromoethers, preparation of, 1008, 1010  
 Bromoethylbenzene, styrene from, 253, 255  
 Bromoethylidene alcohol, hydroxyethyl vinyl ether from, 1008, 1010  
 $\alpha$ -Bromoethylstyrene, polymerization of, 259

- Bromofluorene, reaction with mercury di-*p*-tolyl, 1140, 1141
- Bromofluoroethylene, reactions of, 1042
- Bromoform, reaction with aluminum, 143
- Bromoheptyne, preparation of, 1156
- 6-Bromo-*n*-hexylamine, hexamethylenimine from, 1000
- $\beta$ -Bromohydrocinnamic acid, hardening agent, 618
- 4-Bromo-5-hydroxy-*cis*-3,6-endo-methylenehexahydrophthalic acid, reactions of, 836
- Bromindane, from indene, 98, 102
- $\beta$ -Bromoisobutyric acid, methacrylic acid from, 1080
- Bromomaleic anhydride, condensation with glycerol, 889
- 2-Bromomethylfuran, resin from, 520
- 2-Bromo-2-methyl-1-hydrindone, reactions of, 558
- Bromonaphthalene, from dibromonaphthalene, 1142
- $\beta$ -Bromophenotole, phenyl vinyl ether from, 1008
- p*-Bromophenol, reaction with sulphur dichloride, 1184
- Bromoprene, formation of, 149, 159
- , polymerization of, 170, 171
- , reaction with fumaric acid, 160
- , — maleic anhydride, 160
- , stretched, x-ray pattern of, 90
- $\alpha$ -Bromopropionaldehyde dimethyl acetal, oxidation of, 1070
- $\alpha$ -Bromopropionic acid, acrylic acid from, 1070
- , reaction with phenol-aldehyde resins, 427
- Bromosalicylaldehyde, condensation with 4,6-dinitro-*m*-xylene, 726
- Bromostryrene, from phenylethanol, 254, 255
- , polymerization of, 255
- Bromovinylacrylic acid, polymerization, 1085
- Bronze dies, use of, 1296
- Bronze-iron, inhibitor, polymerization of vinyl bromide, 1037
- Bronze powder, incorporation in, urea resins, 644
- Bronzing, metallic surfaces, 1251
- Bronzing liquids, preparation, 129, 1026
- Brown-coal tar, styrene from, 256
- Brownian movement, effect in moving liquid, 70
- , influence on plasticity, 33
- , of chloroprene particles, 157
- Brucidine, resins from, 745
- Brush-binder, cresylic acid-formaldehyde resin as, 368
- Brushing, of chlororubber paints, 1118
- , of Glyptal lacquers, 955, 961
- B-stage alkyl resins, in coating compositions, 964
- B-stage resins, resists, 307
- Buffer compounds, in urea-formaldehyde condensation, 611
- Buffering, of urea-formaldehyde reaction, 597, 637
- , of phenol-formaldehyde reaction, 353
- Buffer mixtures, condensing agents, 589
- Buffers, use in isoprene polymerisation, 178
- Buffing wheels, use in finishing moldings, 1330, 1331
- Bulk factor, of molding materials, 1356
- Bulking value, of chlororubber, 1118
- Bureau of Standards, investigations on testing, 1340
- Butadiene, ammonium oleate emulsifier for, 178
- , by cracking, 201
- , co-polymerization with acrylic acid derivatives, 1076
- , —  $\alpha$ -methylstyrene, 193
- , — monolefins, 192
- , — stand oil, 199
- , — styrene, 245, 251
- , — vinyl esters, 1034
- , from acetone-vinyl bromide reaction, 1253
- , from 1,3-butylene glycol, 178
- , from destructive distillation of coal, 185
- , from ethylene, 165
- , from petroleum fractions, 176
- , halogenated, resinous materials from, 170, 171
- , oxidation with nitric oxide, 727
- , polymerisation of, 168, 169, 170, 176, 178, 183, 184, 198, 1100
- , —, acetic acid catalyst, 175, 180
- , —, aluminum catalyst, 185
- Butadiene, polymerization of, arsenious acid catalyst, 180
- , —, iodine catalyst, 180
- , —, iron catalyst, 185
- , —, nickel catalyst, 185
- , —, oxygen catalyst, 179, 180
- , —, polyvinyl ethers as acids, 1011
- , —, sodium catalyst, 176, 178, 181-184
- , —, polymerized, coating composition from, 182
- , —, in admixture with rubber and sulphur, 198
- , —, sulphonation of, 1100
- , —, use with alkyl resins, 942
- , —, Polynit from, 178
- , —, preventing resinification of, 1104
- , —, reaction with acrolein, 831
- , —, benzoquinone, 832
- , —, crotonaldehyde, 832
- , —, 5,8-di-hydroxy-1,4-naphthoquinone, 834
- , —, 3,6-endomethylene- $\Delta^4$ -tetrahydrophthalic anhydride, 836
- , —, maleic anhydride, 832
- , —, methylacetylene dicarboxylate, 834
- , —, mucic acid, 834
- , —, naphthazarine, 834
- , —,  $\alpha$ -naphthoquinones, 833
- , —, sorbic acid, 834
- , —, unsaturated nitriles, 850
- Butadiene derivatives, polymerization of, 169-174
- , —, polymerization of, effect of light, 171
- , —, polymerisation of, effect of substituting groups, 169, 170, 171
- , —, structure of polymers from, 171, 173, 174
- Butadiene hydrocarbons, condensation with aromatics, 193, 194
- , —, polymerization of, 168-185, 195, 196, 198
- , —, polymerized, condensation with rosin-ethylene oxide resin, 200
- , —, crimping fibers from, 200
- , —, hardening of, 199
- , —, mixed with balata, 200
- , —, mixed with gutta-percha, 200
- , —, mixed with rubber, 197, 198, 200
- , —, sulphurizing of, 1101
- , —, vulcanisation of, 181, 185, 195, 196
- Butadiene polymers, artificial glass from, 199
- , as bonding agents, 200
- , halogenated, use of, 199
- , in insulating compositions, 828
- , in paint, 184
- , in rubber compositions, 198
- , solvents for, 184, 199
- , stability of, 178
- , structures of, 170, 172
- , vulcanization of, 195
- , vulcanized, as electrical insulation, 197, 198
- Butadiene-vinyl halide co-polymers, hydrolysis, 1057
- 1,3-Butadienol, preparation of esters of, 151
- Butadienol-ester polymers, applications of, 152
- Butadienol esters, polymerization of, 152
- Butane, from vinylacetylene, 149
- , liquid, purification of rosin, 768
- Butanol, see Butyl alcohol.
- 1-Butene, from ethylene, 165
- 1-Butene-3-one, formation of, 149
- Butenyne, see Monovinylacetylene
- $\beta$ -Butoxyethyl  $\beta$ -hydroxyethyl phthalate, plasticizer, 897
- Button method, locating holes in molds, 1301
- Buttons, from lignite-phenol resins, 275
- , from polyvinyl resins, 1029
- , from urea resins, 623, 627
- Butyl abietate, plasticizer for phenolic resins, 829
- , preparation of, 798, 801
- Butyl acetate, in paint removers, 903
- , modifier, dihydroxybenzophenone-aldehyde resins, 374
- , —, polymerization of ethyl acrylate in, 1078
- , —, solvent, for alkyl resins, 967, 968
- , —, for ester gum, 822
- , —, for natural resin, 632
- , —, for nitrocellulose, 412
- , —, for Olvine, 1033
- , —, for phenol-aldehyde resins, 431, 445, 446, 532

Butyl acetate, solvent, for polystyrene, 236  
 —, —, for vinyl acetate polymers, 1024  
 —, —, for vinyl co-polymers, 1047  
 —, use in laminated glass adhesive, 718  
 Butyl acetate-toluene mixture, solvent for Rezyls, 956  
 Butyl acrylate, use in polymerization of diolefins, 181  
 Butyl alcohol, colloidal dispersions of phenol-oil-formaldehyde resin in, 404  
 —, dehydrating agent, 601, 675  
 —, esterified with dibenzenesulphonylarginine, 722  
 —, —, rosin, 797  
 —, —,  $\alpha$ -terpinene-maleic anhydride, 844  
 —, modifier, phenol-aldehyde resins, 374, 416  
 —, reaction with glyceryl phthalic acid, 903  
 —, —, phenol-aldehyde resins, 310  
 —, —, phthalic anhydride, 902  
 —, solvent, for hydrogenation of esters, 807  
 —, —, for resins, 405, 412, 446, 565, 612, 630  
 —, use with alkyd resins, 925, 967  
 —, —, nitrocellulose lacquers, 412, 967  
 Butylamine, catalyst, for phenol-formaldehyde reaction, 347  
 —, —, condensation with butyraldehyde, 707  
 —, —, heptaldehyde, 707  
 —, —, propionaldehyde, 707  
 —, reaction with carbon disulphide, 1197  
 n-Butylaniline, condensation with formaldehyde, 687  
 Butylbenzene, condensation with ethylene dihalides, 266  
 —, —, isoprene, 194  
 n-Butylbenzoyl-o-benzoic acid, salts of, 953  
 Butyl cellosolve, solvent, for Rezyls, 966  
 —, —, for phenol resin, 445, 446  
 Butyl cellulose, with ester gum in lacquers, 824  
 p-ter-Butyl-m-cresol, use in modified alkyd resins, 936  
 5-Butyl-1,3-cyclohexadiene-6-caprylic acid, dimeric, from tung oil, 1216  
 —, monomeric, from tung oil, 1216  
 2-Butyl- $\Delta^3,5$ -cyclohexadienyl-octanoic acid, from eleostearic acid, 860  
 Butyl esters of shellac, plasticizers for cellulose ester compositions, 823  
 Butyl monoethylvin phthalate, plasticizer, for nitrocellulose, 900  
 Butyl palmitate, modifier, phenol-aldehyde resins, 430  
 Butyl phthalate, modifier, for phenol-aldehyde resins, 399, 400  
 —, plasticizer, for urea resin varnish, 632  
 —, solvent, for cellulose esters, 960  
 Butyl propionate, solvent for resins, 445, 446, 967  
 Butyl stearate, modifier, phenol aldehyde resins, 424  
 —, plasticizer, for polystyrene, 247  
 —, —, vinyl resins, 1050  
 Butylene, reaction with sulphur monochloride, 1179  
 n-Butylene acetone, condensation with aldehydes, 550  
 —, from acetone and n-butyraldehyde, 550  
 Butylene esters, of phenylacrylic acid, polymerization, 1083  
 Butylene glycol, butadiene from, 178  
 —, condensation with castor oil-maleic anhydride product, 855  
 —, —, urea, 659, 664, 665  
 —, —, thiourea, 659  
 —, reaction with adipic acid, 898  
 —, —, maleic acid, 855  
 —, —, maleic anhydride, 898, 909, 1029  
 —, —, phenols, 393  
 —, —, phthalic anhydride, 893  
 —, synthesis of, 178  
 —, use in preparation of alkyd resins, 969  
 Butylenedianilide, rubber accelerator, 707  
 i-Butylene, see Isobutylene.  
 n-Butylisourea, preparation of, 571  
 p-ter-Butylphenol, reaction with formaldehyde, 376  
 p-Butylphenol-aldehyde resins, modifiers, for phenol-aldehyde resins, 427  
 Butyl- $\alpha$ -terpinene-maleate, formation of, 844

Butyl vinyl ether, polymerization of, 1010  
 n-Butyl zinc phthalate, preparation of, 952  
 —, use with nitrocellulose, 950  
 Butyraldehyde, condensation with acetone, 550  
 —, —, aniline, 705, 706, 707  
 —, —, butylamine, 707  
 —, —, dinaphthylamine, 709  
 —, —, diphenylamine, 709  
 —, —, sym-diphenyl-p-phenylenediamine, 709  
 —, —, phenol, 301, 382  
 —, —, phenyl- $\beta$ -naphthylamine, 709  
 —, —, polyvinyl alcohol, 1061  
 —, —, polyvinyl ester, 1062  
 —, —, o-tolylguanidine, 707  
 —, —, o-toluidine, 707  
 —, —, vinyl compounds, 1064  
 —, in rubber accelerators, 705  
 —, polymerization of, 505  
 —, reaction with sodium vinylacetylide, 151  
 —, stabilization of, 497  
 Butyraldehyde-phenol resins, hardening agents for, 382, 632  
 Butyric acid, condensing agent, amines and aldehydes, 707  
 —, reaction with polyvinyl alcohol, 1059  
 —, —, vinylacetylene, 151  
 —, use with alkyd resins, 905, 906, 935  
 Butyrylacetophenone, condensation with salicylic aldehyde, 557  
 Butyric anhydride, reaction with polyvinyl alcohol, 1057  
 By-product coke ovens, use of, 360  
 By-product gases, urea from, 586  
 By-products, in cuprene formation, 145  
 —, resinous, purification of coal-tar distillates, 120, 121

## C

Cable insulation, methyl rubber, 178  
 —, polystyrene resin, 249, 250, 251  
 —, resin-impregnated laminated sheets, 472, 473  
 —, rubber, 1092  
 —, styrene copolymers, 251  
 —, submarine, 1091  
 Cables, lead, extrusion of, 1323  
 Cacodylic acid, modifier, phenol-aldehyde resins, 440  
 —, toxic agent, 451  
 Cadmium, plasticity of, 31, 32  
 —, reaction with urea-alcohol resins, 664  
 Cadmium iodide, use of, 484  
 Cadmium resinate, catalyst, rosin esterification, 794  
 Cadmium salts, catalysts, phenol-acetylene resins, 385  
 —, —, reaction of acetylene and acids, 1018  
 Calcined magnesite, filler, 461  
 Calcium, catalyst, polymerization of 1,3-dienes, 182  
 —, reaction with urea-alcohol resins, 664  
 Calcium acetate, catalyst, formaldehyde condensation, 512  
 Calcium alginate, use, safety glass, 1254  
 Calcium alloy, catalyst, in polymerization of 1,3-dienes, 182  
 Calcium sec.-amylbenzoyl-o-benzoate, preparation of, 933  
 Calcium benzenesulphonate, use, phenol-aldehyde resins, 372  
 Calcium bisulphate, prevention of varnish-yellowing, 1378  
 Calcium bromide, catalyst, phenol-formaldehyde reaction, 357  
 Calcium carbide, acetylene from, 142, 161  
 —, reaction with hydrochloric acid, 1036  
 Calcium carbonate, catalyst, condensation of urea and formaldehyde, 591  
 —, —, formaldehyde condensation, 512  
 —, gelatinous, preparation; of, 30  
 —, modifier, phenol-aldehyde resins, 436  
 —, use, in purification of naphtha, 117  
 Calcium chloride, catalyst, furfural-aniline reaction, 535  
 —, —, phenol-formaldehyde reaction, 317, 356  
 —, —, polymerisation of glycidol, 994  
 —, —, preparation of vinyl chloride, 1035

- Calcium chloride, condensing agent, hydrocarbon-aldehyde resin, 265  
 —, —, urea and formaldehyde, 616, 617  
 —, dehydrating agent, 405, 1125  
 —, fluxing agent, urea resins, 593  
 —, hardening agent, 357  
 —, use, with phenol-aldehyde resins, 372  
 Calcium cresolate, catalyst, phenol-formaldehyde reaction, 355  
 Calcium cyanamide, leaching of, 681  
 —, reaction with calcium sulphide and carbon dioxide, 652  
 —, —, hydrogen sulphide and ammonia, 651  
 —, rosin esterification with, 794  
 Calcium glycerate, use in alkyd resins, 929  
 Calcium hydroxide, catalyst, formaldehyde condensation, 512  
 —, —, phenol-alcohol resins, 332, 333  
 —, condensing agent, formaldehyde and acetaldehyde, 900  
 —, effect on resin formation, 623  
 —, hardening catalyst, furfural-cresol resin, 529  
 —, in carbohydrate-phenol resins, 759  
 —, modifier, phenol-aldehyde resins, 436, 437  
 —, precipitation of resins by, 695  
 —, resin purification with, 337  
 —, retardation of solidification process, urea resins, 617  
 Calcium hypochlorite, oils chlorinated with, 1221  
 Calcium naphthenate, preparation, 206, 209  
 —, uses, 206, 207  
 Calcium nitrate, prevention of varnish-yellowing, 1378  
 —, use of, 637  
 Calcium oleate, modifier, 400  
 —, solubility of transformer oil, 787  
 Calcium oxide, catalyst, aldol polymerization, 499  
 —, —, furfural-phenol reaction, 528  
 —, —, lignin-furfural condensation, 748  
 —, —, rosin esterification, 800  
 —, —, rosin-modified phenol resin, 398  
 —, —, resinification of triphenyl phosphate, 432  
 —, hardening catalyst, alkyd resins, 881, 980, 981  
 —, —, phenol-furfural resin, 529  
 —, —, phenol-glycerol resin, 393  
 —, modifier, phenol-aldehyde resins, 436-437  
 —, resin purification with, 337  
 —, use in cumarone polymerization, 117, 119  
 —, use in vulcanization of synthetic rubber, 197  
 —, use with chlorinated rubber, 1107, 1108  
 Calcium phenolate, hardening catalyst, phenol-glycerol resin, 393  
 Calcium phosphate, use in preparation of butadiene, 178  
 Calcium polysulphide, reaction with ethylene dichloride, 1173  
 —, reaction with isoprene dibromide, 1171  
 Calcium resinate, catalyst, esterification of Congo-rosin mixture, 811  
 —, modifier, 400  
 —, rosin esterification with, 794  
 Calcium salicylate, use with phenol-aldehyde resins, 372  
 Calcium salts of alkyd resins, 946, 949  
 Calcium soaps, modifiers, phenol-aldehyde resins, 438  
 —, tall oil, 755  
 Calcium stearate, mold lubricant, 620  
 —, stabiliser, vinyl-ester co-polymers, 1067  
 Calcium sulphate as filler, aldehyde-tar-acid resin, 364  
 —, phenol-aldehyde resins, 317, 318  
 Calcium sulphide, use, lustrous paints, 1125  
 Calcium sulphonate, varnish constituent, 219  
 Calcium tetrasulphide, reaction with olefin halides, 1173  
 Calcium thiocyanate, modifier, syntans, 420  
 —, with urea resin, 660  
 Camphane, reaction with formaldehyde, 782  
 Camphene, co-polymerisation with diolefins, 192  
 —, esterification with polycarboxylic anhydrides, 814  
 —, modifier, phenol-aldehyde resins, 433  
 —, reaction with acetyl chloride, 1139  
*a*-Campholenic aldehyde, resinification of, 510, 511  
 Camphor, adhesive for safety glass, 719  
 —, combination with polyvinyl chloride, 1038  
 —, from linalool, 783  
 —, incorporation in vinyl resins, 1022  
 —, in safety glass, 644, 829  
 —, modifier, chlororubber, 1108  
 —, —, dihydroxybenzophenone-aldehyde resins, 374  
 —, —, phenol-aldehyde resins, 428, 430, 441  
 —, —, urea-furfural resins, 669, 670  
 —, plasticizer, chlororubber, 1123, 1126  
 —, —, diphenylolpropane-formaldehyde resin, 388  
 —, —, phenol-aldehyde resin, 285, 423  
 —, —, styrene molding resin, 245  
 —, —, urea-formaldehyde resins, 601  
 —, —, vinyl resins, 1029, 1050  
 —, pyrolysis, polymerization, 558  
 —, reaction with formaldehyde, 559  
 —, reaction with furfural, 525  
 —, urea resin lacquers with, 632  
 Camphorene, from linalool, 783  
 Camphoresmic acid, from turpentine resin, 1253  
 Camphoric acid, 884  
 —, in alkyd resins, 893, 935  
 Camphoric anhydride, in alkyd resins, 908  
 Camphorin, from glycerol and camphoric acid, 893  
 Camphor oil, modifier, urea-phenol-aldehyde resins, 674  
 —, resins from, 262  
 —, softening agent, phenol-aldehyde resins, 429  
 Camphor substitute, amine-aldehyde resins, 695  
 —, nitro resins, 728  
 —, *p*-toluenesulphonamide, 719  
 Cam presses, uses of, 1311  
 Canada balsam, incorporation into alkyd resins, 943  
 —, in non-splintering glass, 963  
 —, in urea-phenol-aldehyde adhesive, 676  
 Canada balsam substitute, amine-aldehyde resin, 701  
 Canal rays, action on hydrocarbons, 269  
 Candles, alkyd resin coatings for, 964  
 Cane sugar, esterifying agent, copal-rosin mixture, 810, 811  
 Cane trash, impregnated, 1245  
 Cannizzaro reaction, 293, 489, 494  
 Canvas, impregnation with phenol resin, 471  
 —, waterproofing of, 360  
 Canvas-base materials, tests on, 1352  
 Caoutchouc molecule, structure of, 1089  
 Capacitance, determination of, 1348  
 Capillary analysis, resins, 1261  
*ε*-Caprolactone, formation of, 1002  
 Caproylphthalimide, decomposition, 853  
 Capryl alcohol, use in castor oil-maleic compositions, 909  
 Carbalkoxybenzenes, condensation with butadiene, 194  
 Carbamide system, tautomerism of, 569  
 Carbazole, introfier for sulphur, 1165  
 —, reaction with olefins, 194, 195, 744  
 —, resinification, 744  
 Carbenes, from petroleum, 201, 302  
 Carbitol, in transfer compositions, 829  
 Carbocyclic liquids, use of, 469  
 Carboids, from petroleum, 202  
 Carbolio acid, *see* Phenol  
 Carbolites, properties of, 35  
 Carbohydrate resins as lacquers, 758  
 Carbohydrates, condensation with polybasic acids, 877  
 —, constitution of, 757  
 —, effect on urea-formaldehyde condensations, 616  
 —, esterification of rosin with, 796  
 —, from formaldehyde, 512, 757  
 —, humic acid derivatives from, 760  
 —, modifiers, phenol-aldehyde resins, 371, 430  
 —, —, syntans, 421  
 —, use in alkyd resins, 877  
 Carbon, active, condensation of urea and formaldehyde, 593  
 —, —, polymerisation catalyst, 226  
 —, cuprene as a substitute for, 146  
 —, formation in acetylene polymerisation, 143  
 —, from charred phenol-formaldehyde resins, 368

- Carbon, molded articles coated with, 484  
 —, use in vulcanizing synthetic rubber, 181, 195  
 Carbon arc exposure cabinet, 1870  
 Carbonate pigments, reaction with alkyl resins, 973  
 Carbonates, modifiers for fatty oils, 1237  
 Carbon black, filler, olefin-polysulphide rubber, 1174  
 —, use in rubber composition, 197, 1094  
 —, use in vulcanisation of synthetic rubbers, 195, 196  
 Carbon dioxide, catalyst, acrylic acid polymerization, 1070, 1071  
 —, —, drying oil polymerization, 1225  
 —, —, phenol-formaldehyde resins, 349, 350  
 —, condensation with phenols, 374  
 —, dissolution in polystyrene, 237  
 —, effect in rosin ester formation, 794, 795  
 —, in benzyl chloride condensation, 1130  
 —, in polymerization of glycerol, 996  
 —, purification of resins with, 335  
 —, removal of water, urea-formaldehyde resins, 601  
 —, use in alkyl resin production, 922, 923, 929, 931  
 —, use in molding, 464, 1334  
 —, use in polymerization of 1,3-dienes, 175, 177, 182  
 —, use of, 352, 365  
 Carbon disulphide, carbon subsulphide from, 1015  
 —, catalyst, phenol-formaldehyde reaction, 345, 346  
 —, reaction with alkali cellulose, 1197  
 —, —, amine-aldehyde condensation products, 707  
 —, —, amines, 652, 1197  
 —, —, dimethylketene, 553  
 —, solvent, chloroprene polymerization, 157  
 —, —, o-cresol-formaldehyde resin, 367  
 —, —, halogenated rubber, 1105  
 —, —, petroleum resins, 202  
 —, vulcanization accelerators from, 1197  
 Carbon disulphide-piperidine, hardening agent for shellac, 703  
 Carbonic acid, neutralizing agent, 319  
 Carbonic acid derivatives, esterification with ethylene glycol, 862  
 Carbonization of phenol-aldehyde resin, 488, 982  
 Carbon monoxide, effect of electrical energy on, 1012, 1013  
 —, formamide from, 566  
 —, from lactic acid, 1003  
 —, reaction with acetylene, 161  
 —, —, ammonia, 684  
 —, —, hydrogen, 552, 1255  
 Carbon monoxide-hydrogen reaction, resins from, 1255  
 Carbon oxides, solid, formation of, 1013  
 Carbon oxydisulphide, reactions with dimethylketene, 553  
 —, urea from, 567  
 Carbon paper, use of synthetic resins, 452, 827, 1246  
 Carbon remover, chloronaphthalene as, 1153  
 Carbon suboxide, 1012-1015  
 —, polymerization of, 1013-1015  
 —, preparation of, 1012-1014  
 Carbon subsulphide, polymerization of, 1015  
 Carbon tetrachloride catalyst, furfural-phenol condensation, 527  
 —, catalyst, rosin esterification, 800  
 —, chlorination medium, 160, 1151, 1154, 1220  
 —, effect on chloroprene rubber, 158  
 —, —, pyrolysis of ethylbenzene, 254  
 —, —, styrene polymers, 246  
 —, solvent for chloroprene, 159  
 —, —, o-cresol-formaldehyde resin, 367  
 —, —, halogenated rubber, 1105, 1118  
 —, polymerization of ethylene oxide, 993  
 —, polyvinyl chloride, 1033  
 —, rosin derivatives, 777  
 —, rubber, 1092  
 —, use in polymerization of 1,3-dienes, 180  
 —, use in purification of phenol-aldehyde resins, 362  
 —, use in rubber-chlorination, 1109, 1110  
 Carbon transfers, use of, 483  
 Carbonyl compounds, effect on styrene polymerization, 341  
 Carbonyl groups in shellac, 1006  
 Carbonyls, catalysts, polymerization of styrene, 242  
 Carborandum, binder for, 986, 1288  
 Carborandum, filler, phenol-aldehyde resin, 460  
 —, use in chlororubber paint, 1125  
 Carbostyryl, from quinoline, 739  
 4-Carboxy-2,6-dimethylmandelic acid, lactide from, 1003  
 Carboxylated phenol-aldehyde resins, 427, 429  
 Carboxyl group in rosin, 765  
 Carboxylic acid-boron trifluoride complex, catalyst, cumarone polymerization, 119  
 Carboxylic acids, condensation with acetylene, 161  
 —, gelatinization inhibitors, 787  
 —, reaction with carbon suboxide, 1012  
 —, —, vinylacetylene, 151, 152  
 Carboxylic anhydrides, action on rubber, 1100  
 o-Carboxyphenoxycetic acid, resins from, 736  
 2-Carboxyphenylthioglycolic acid, 894  
 Carburetted water-gas, styrene from, 97, 257  
 Carburetted water-gas tar, resins from, 121  
 Cardanol, formula for, 1229  
 Cardboard linings, polymerization apparatus, 179  
 Cardboard products, urea resins in, 626  
 Cardol, from cashew shells, 1229  
 Cardolite, from cashew shell oil, 1229, 1232  
 Carnauba wax, combination with rosin and sulphur, 1164  
 —, modifier, phenol-aldehyde resins, 425, 426  
 —, reaction with acetone, 541  
 —, use, mold-lubricant, 1327  
 —, use with chlororubber, 1133  
 —, use with coal-tar bitumen, 360  
 Carnauba-wax acid, acylation of phenol-aldehyde resins, 426  
 Carnaubyl alcohol, reaction with fatty acids, 1233  
 Carrageen moss, emulsification of 1,3-dienes, 180  
 "Carrier substances," in urea-aldehyde resins, 679  
 Carvaerol, reaction with furfural, 525  
 —, reaction with malic acid, 1254  
 Carvene, reaction with phenol, 783  
 Carvone, reaction with formaldehyde, 559  
 —, reaction with oxygen, 558  
 Caryophyllene, reaction with ethyl diazoacetate, 783  
 Casein, artificial horn from, 415, 416  
 —, artificial, modified urea-aldehyde resin, 665  
 —, carrier, in urea-aldehyde resins, 679  
 —, cold-molding compositions, 1255  
 —, combination with vinyl acetate, 1033, 1034  
 —, condensation with acetaldehyde, 782  
 —, —, phthalic anhydride, 732  
 —, effect of glyoxal, 507  
 —, effect of tanning agents on, 200  
 —, extrusion of, 1323  
 —, filler, phenol-aldehyde resins, 318  
 —, —, sulphur castings, 1166  
 —, incorporation with alkyl resins, 943, 944  
 —, —, urea resins, 625  
 —, ingredient of gutta-percha substitute, 1205  
 —, in rosin compositions, 778  
 —, modifier, biuret-cyanuric acid-formaldehyde resin, 685  
 —, —, dicyanodiamide-formaldehyde resin, 680  
 —, —, phenol-acetone resins, 417  
 —, —, phenol-aldehyde resins, 317, 415-418, 430  
 —, —, polyvinyl acetals, 1064  
 —, —, urea-phenol-aldehyde resin, 688  
 —, —, urea resins, 609, 664, 678-680, 684  
 —, molding, use of horn, 1249  
 —, molding composition, containing methylol butyl urethane, 682  
 —, —, use of urea, 678  
 —, moldings from, 1333  
 —, plastics from, 33  
 —, reaction with dimethylolurea, 679  
 —, —, phenol and aldol, 417  
 —, softening agent for, 910  
 —, use, adhesive, 1246  
 —, —, gas envelopes, 1247, 1248  
 —, —, in alkyl resins, 944, 946, 949, 954  
 —, —, in alkyl resin emulsions, 948, 977  
 —, —, in chloroprene rubber latex, 157  
 —, —, in urea resin coating, 683  
 —, —, stabilising resin suspensions, 1251  
 —, —, with isoprene polymer, 200  
 —, —, with urea resin, 631  
 Casein-benzyl chloride condensation, 1133

- Casein-furfural reaction, resin from, 538  
 Casein glue, acetaldehyde with, 495  
 Casein-urea mixture, artificial horn, 679  
 Casheew-shell oil, combination with sulphur, 1164  
 —, polymerisation, 1229, 1230  
 —, reaction with aldehydes, 277, 1230  
 Casheew-shell oil resins, 1229-1232  
 Cassava starch, filler, sulphur castings, 1166  
 Castable phenol-aldehyde resins, 467-470  
 Casting, effect on transparency of phenol resins, 467  
 —, multi-colored material, 1313, 1314  
 Casting compositions, from sulphur, 1165  
 Casting of resins, methods, 1313, 1314  
 Cast-iron molds, properties of, 1297  
 Castor oil, acetylated, factice from, 1212  
 —, auto-condensation of, 1222  
 —, binder for cold-molding composition, 1236  
 —, combination with polyvinyl chloride, 1038  
 —, condensation with resorcinol, 406  
 —, — glycerol, 802, 1222  
 —, dehydration product, esterification, 1225  
 —, destructive distillation of, 927  
 —, distillation residue, uses of, 826, 1224  
 —, estolide formation, 1221-1224  
 —, in insulating cement, 820  
 —, in stencil sheet, 962  
 —, in urea-resin-nitrocellulose lacquers, 636  
 —, modification, 1227  
 —, modified with synthetic resins, 1223  
 —, modifier, alkyd resins, 157, 646, 874, 905-910, 927, 931, 932, 935, 936, 939, 965-968  
 —, —, acetaldehyde resin, 493  
 —, —, phenol-aldehyde resins, 405, 406, 419, 439  
 —, 9,11-octadecadiene-1-carboxylic acid from, 962  
 —, plasticizer, modified urea-aldehyde resin, 678  
 —, —, phenol-aldehyde resins, 424  
 —, —, wood pulp plastics, 748  
 —, —, urea resin lacquers, 633  
 —, polyester fatty acid glycerides from, 1222  
 —, polymerized with primary aromatic diamines, 1219  
 —, properties of, 909  
 —, reaction with maleic anhydride, 855, 1029  
 —, —, metallic calcium, 1214  
 —, —, phenol-aldehyde resins, 428  
 —, —, polybasic acids, 909, 910  
 —, —, rosin, 803, 910  
 —, —, selenious acid, 1223  
 —, —, resin plasticizer, 909, 1246  
 —, softener in adhesives, 1100  
 —, solvent, petroleum resins, 202  
 —, —, polyvinyl alcohol, 1056  
 —, sulphurized, plasticizer, 1209  
 —, synthetic drying oil from, 802, 1225  
 —, vulcanisation of, 1204  
 —, vulcanized with selenium, 1209  
 Castor oil acids, dehydration of, 910  
 —, esterification with ethyl alcohol, 1224  
 —, lacquer substitutes from, 803  
 —, reaction with oxidized rosin, 803  
 —, use in alkyd resins, 984  
 Castor oil-alkyd resin, modifier, urea-aldehyde resins, 661, 662  
 Castor oil factice, molding composition from, 1214  
 Cast resins, Aroclors as, 1150  
 —, heat-hardening of, 470  
 —, modified urea-formaldehyde as, 671  
 —, phenol-aldehyde as, 286, 287, 328, 369, 419, 1313  
 Catalin, cast phenolic resin, 467, 468  
 Catalysis, trigger molecule theory of, 173  
 —, drying of drying alkyds, 918, 922  
 Catalysts, action in urea resin, 566  
 —, effect of heat on, 254  
 —, effect on copal-glycerol reaction, 809  
 —, —, p-cresol-aldehyde resins, 367  
 —, —, cuprene-formation, 145  
 —, —, furfural resin, 520  
 —, —, phenol-resin varnishes, 445  
 —, —, polymerization, 50  
 —, —, polymerization of vinyl compounds, 164  
 —, —, rate of condensation of phenols, 347  
 —, —, styrene polymerisation, 233-235  
 —, for acetaldehyde production, 496  
 —, for air-oxidation of phenol, 271  
 Catalysts, for benzaldehyde-phenol resins, 278, 279  
 —, for chlorination of biphenyl, 1144  
 —, for chlorination of naphthalene, 1151  
 —, for condensation of benzyl and cinnamic alcohols, 1007  
 —, —, benzyl chloride and trioxymethylene, 299  
 —, for ethyl alcohol oxidation, 496  
 —, for furfural-acetone reaction, 537  
 —, for furfural-aniline reaction, 535  
 —, for hydrogenation of furfural, 519  
 —, for  $\beta$ -nitrostyrene polymerization, 259  
 —, for phenol-alcohol resins, 332, 333  
 —, for phenol-alkyl halide condensations, 1133  
 —, for phenol-sulphur reaction, 1190, 1191  
 —, for polymerization of butadienol esters, 152  
 —, —, 1,3-dienes, 169, 173, 179, 182  
 —, —, ethylene oxide, 991  
 —, —, furfural, 521  
 —, —, glycerol, 428, 995, 996  
 —, —, styrene solutions, 243  
 —, for preparation of vinyl ethers, 1007  
 —, for reaction of benzyl chloride with phenol, 295  
 —, —, sulphur chloride with hydrocarbons, 1200, 1202  
 —, for rosin-aldehyde condensations, 776  
 —, for rosin oil production, 779  
 —, for styrene separation, 254, 255  
 —, for sulphur-aniline reaction, 1197  
 —, hardening, alkyd resins, 980  
 —, —, urea resins, 644  
 —, influence on phenol-formaldehyde reaction, 291, 296  
 —, in urea manufacture, 566  
 —, neutralisation of, 326, 344, 368  
 —, removal from synthetic resins, 1251, 1252  
 —, removal in cumarone polymerization, 117-119  
 —, resins by exclusion of, 318, 319  
 —, styrene from chloroethylbenzene with, 253  
 Catalytic oxidation, acetylene, 496  
 —, ethyl alcohol, 496  
 Catalytic polymerization, of styrene, 238-242  
 Catalytic production of biphenyl, 1142  
 Catavia resin ester, as varnish resin, 823  
 Catechol, anti-aging effect in varnishes, 821  
 —, effect on chloroprene polymerization, 156, 157  
 —, reaction with acetone, 387  
 —, —, formaldehyde, 343  
 —, resin from, 270  
 Catechol-acetone resin, 387  
 Catecholsulphonaphthalein, amorphous properties, 1252  
 Catechol tannins, hardening of phenol-aldehyde resins, 441  
 Catgut ligatures, x-ray studies of, 71  
 Cathode rays, action on rubber, 1104  
 —, polymerisation of acetylene hv, 144  
 Caustic alkalies, catalysts, phenol-alcohol resins, 332  
 —, catalysts, condensation of urea and formaldehyde, 609  
 —, in phenol-carbohydrate condensation, 760  
 Caustic potash, catalyst, acetaldehyde resin, 491  
 —, condensing agent, phenol-aldehyde resin, 279, 288, 289, 343  
 —, condensing agent, saligenin preparation, 281  
 Caustic soda, catalyst, acetaldehyde resin, 490, 492  
 —, catalyst, phenol-formaldehyde reaction, 279, 343, 344, 346, 349, 352, 353, 415  
 —, condensing agent, saligenin preparation, 281  
 —, resins from isoeugenol with, 262  
 —, treatment of phenol-formaldehyde resin with, 434  
 Cedar-nut oils, reactivity with nitric acid, 1233  
 Cedar oil, combination with polyvinyl chloride, 1038  
 Cedar-wood flour, cellulose-urea resin products, 622  
 Cedrene, polymerization, 733  
 Cellobiose, structure of, 63  
 Cellophane, alkyd resins bonding agents for, 977  
 —, alkyd resin coatings for, 965  
 —, polyacrylic esters with, 1077  
 —, toluenesulphonamide resin with, 721  
 Cellulosolve, solvent, 402, 408, 456, 634, 969  
 —, —, cold-molding composition, 1238

- Cellosolve, solvent, Teglaes, 956
- , —, urea-resin lacquer, 636
- Cellular materials, impregnation with amine-aldehyde resins, 698
- Celluloid, adhesives for, from terpinene, 763
- , coloring of, 1250, 1251
- , effect of ester gum in, 829
- , extrusion of, 1323
- , moldings, 454, 1319, 1331
- , polyalkylene oxide plasticizer for, 993
- , resin cements, 718
- , softening agent for, 910
- , use in shatterproof glass, 719, 1283
- Celluloid substitutes, alkyd resins as, 874
- , butadiene polymers, 170, 198
- , from rubber, 1083
- , modified chlororubber, 1124
- , olefin sulphones, 1178
- , phenol-aldehyde resins, 285, 414
- , polyvinyl acetals, 1061, 1062, 1066
- , polyvinyl chloride, 1087, 1040
- , synthetic resin composition, 1246
- Cellulose, action of naphthene anhydrides, 208
- , affinity for urea resins, 564, 620
- , amorphous nature of, 64, 66
- , filler, phenol-aldehyde resins, 352, 371
- , —, sulphur castings, 1166
- , —, urea resins, 584, 595
- , incorporation with amine-aldehyde resins, 693
- , —, urea resins, 616, 620, 626, 640, 656, 679
- , —, vinyl resins, 1030
- , in tanning compounds, 750
- , modifier, phenol-formaldehyde resins, 415
- , —, urea-aldehyde resins, 684
- , molecular weight of, 75
- , plastic gel from, 66
- , reactions of, 64, 749, 750 ✓
- , reaction with dicarboxylic acids, 904
- , —, ethylene oxide, 900
- , —, hydrazine, 735
- , —, sodium zincate, 434
- , regenerated, Aroclor resins in, 1150
- , —, electrical insulation, 1243
- , —, lacquer for, 1243
- , —, stamps for, 200
- , resins from, 900, 1234
- , specific viscosity of, 74, 75
- , structure of, 56, 63, 64, 66
- , tensile properties of, 71
- , treated with chlorides of estolidic acids, 1222
- , use in phenol-aldehyde lacquer, 433, 434
- , use in polymerization of 1,3-dienes, 182
- , X-ray studies of, 56, 63, 70
- α-Cellulose, incorporation with urea resins, 620
- , in molding compositions, 958
- Cellulose acetate, binder for abrasives, 1275
- , compatibility with aniline-furfural resins, 701
- , —, chlorinated rosin, 803
- , —, formaldehyde-diphenylolcyclohexane resin, 377
- , —, natural resins, 966
- , —, phthalic-glycol, 897
- , —, Plasto resins, 966
- , —, resorcinol-acetone resin, 373
- , —, Resyl balsams, 966
- , —, Santolites, 966
- , extrusion of, 1323
- , filler, urea resins, 623
- , flow of, 1330
- , gelation of, 89
- , incorporation with aniline-furfural resin, 701
- , —, benzoylbenzoic glyceride, 894
- , —, phenol-formaldehyde resin, 701
- , polyvinyl acetate, 1027
- , urea resins, 623
- , in floor covering, 984
- , injection molding of, 1324
- , in lacquers, 825, 969
- , in safety-glass adhesive, 373
- , phenol resin varnishes with, 446, 452
- , plasticisers for, 820, 722, 970
- , polyvinyl-alcohol coating, 1058
- , use as glass substitute, 1245
- , use in decorative overlays, 1333
- , use in insulating material, 970
- Cellulose acetate, use in linoleum, 198
- , use in sound records, 1336, 1338

- Cooling molds, before removing molding, 1295, 1320
- Cooling press, use of, 1323, 1329
- Copaiba balsam, combination with polyvinyl chloride, 1038
- Copaiba resin, modifier, phenol-aldehyde resin, 398
- Copal-alkyds, compatibility with nitrocellulose, 913
- Copalamide, by copal-acetamide reaction, 810
- Copal esters, advantages over copals, 816
- , in oil varnishes, 816, 819
- , of polyhydroxy fatty acids, 829
- , preparation of, 807-811
- , resins from, 804
- , varnish from, 807, 817, 819
- Copal oil, esterification with Congo copal, 809
- Copal-rosin mixtures, esterification of, 810, 811
- Copals, combination with polyvinyl acetate, 1032
- , condensing medium, urea resins, 617
- , cracking of, 808
- , esterification of, 807-811
- , —, effect of linseed oil, 809
- , —, effect of rosin, 810
- , esterified with high-boiling esters, 809, 810
- , gelation of, 808
- , in cold-molding compositions, 1286, 1287
- , incorporation into alkyd resins, 943
- , liming of, 773
- , modifiers, phenol-aldehyde resins, 396, 397, 408
- , molding of, 1314
- , nitration, resins from, 731
- , oxidation of, 774
- , polymerisation, 807, 808
- , pressboard from, 470
- , production of, 18, 812, 813
- , progress of esterification of, 808
- , reaction with acetamide, 810
- , reaction with creosote oil, 810
- , shellac substitute from, 1006
- , substitutes, amine-aldehyde resin, 699
- , —, ester gum, 816
- , —, phenol alcohol resins, 287
- , sulphurised, gutta-percha substitute, 1205
- , treatment with naphthalene, 809
- , treatment with phenols, 809, 810
- , use in alkyd resins, 908
- , use in molded insulation, 986
- , use in urea-formaldehyde-alkyd compositions, 940
- Co-polymerization, 42, 43
- , complexes by, 243, 244
- , olefins and diolefins, 189-193, 225
- Co-polymers, acrylic acid derivatives, 1075, 1076
- , styrene, 234, 245, 246, 250, 251, 1072
- , vinyl resins, 251, 1016

- Copper, action on benzyl chloride, 1130  
 —, action on iodo compounds, 1142  
 —, catalyst, acetylene polymerization, 143-146  
 —, —, air-oxidation of phenol, 271  
 —, —, ammonia-carbon monoxide reaction, 684  
 —, —, cashew-shell oil, reaction with aldehyde, 1231  
 —, —, cumarone polymerization, 118  
 —, —, drying oil polymerization, 1228  
 —, —, hydrocarbon-halide condensations, 1138  
 —, —, paraffin-alginic acid reaction, 1254  
 —, —, rosin esterification, 795, 802  
 —, —, separation of styrene, 254  
 —, coating for molded articles, 484  
 —, component of hopcalite, 497  
 —, inhibitor, vinyl ester-aldehyde reaction, 1064  
 —, molding of rubber against, 1326  
 —, oxidation catalyst, 209, 210  
 —, reaction with cashew-shell oil, 1230  
 Copper alloy, catalyst, acetylene polymerization, 144, 146  
 Copper ammonium carbonate, anticorrosive in urea manufacture, 566  
 Copper-bronze, catalyst, reaction of benzyl chloride and phenol, 295  
 Copper carbonate, catalyst, cashew-shell oil reaction with aldehydes, 1231  
 —, —, condensation, urea and formaldehyde, 591  
 —, —, phenol-formaldehyde reaction, 356  
 —, resin pigment, 591  
 Copper chromate, catalyst, hydrogenation of esters, 807  
 Copper chromite, catalyst, ethanol-acetaldehyde condensation, 495  
 Copper compounds, stabilizing action on vinyl esters, 1025  
 Copper ferrocyanide, catalyst, acetylene polymerization, 145  
 Copper hydroxide, resin purification with, 337  
 Copper linseed diglyceride phthalate, 951  
 Copper molds, effect of vinyl-halide resins, 1326  
 Copper monoalkyl phthalic acid, 950  
 Copper naphthenates, 206  
 Copper oleate, catalyst, acetylene polymerization, 146  
 —, catalyst, reaction of cashew-shell oil with aldehydes, 1231  
 —, effect on rubber, 1109  
 —, oxidation catalyst, 210  
 —, solubility in transformer oil, 787  
 Copper oxide, catalyst, acetylene polymerization, 146  
 —, polymerization of castor oil with, 1223  
 —, resin purification with, 337  
 Copper oxide sols, 311  
 Copper-pyridine catalyst, 1139  
 Copper salts, action on pine tar, 731  
 —, alkyl resins, 949  
 —, catalysts, polymerization, vinyl chloride, 1038  
 —, —, reaction of calcium carbide and hydrochloric acid, 1036  
 —, dyes, uses of, 1250, 1251  
 —, neutralizing agents, 344  
 —, sulfonated cumarone resins, use of, 121  
 —, toxic agents, 451  
 —, vinylacetylene, 149  
 Copper soaps, in toxic coatings, 789  
 Copper sulphate, catalyst, condensation of urea and formaldehyde, 616  
 —, catalyst, glycerol resinification, 393, 504  
 —, hardening agent, 357  
 —, in phenol-formaldehyde condensation product, 310  
 —, use, dievanodiamide-formaldehyde reaction, 680  
 Copper wire, coatings for, 407  
 Coral, substitute, 285, 591  
 Coral lime, in hardening rosin, 772  
 Core-binding composition from tall oil, 756  
 Core oil, from rosin and linseed oil, 821  
 Cores, induction coils, from phenol-aldehyde molding powders, 460  
 —, porous, in molded panel, 1333  
 —, removable, synthetic-resin container, 1252  
 —, solid carbon dioxide, 1334  
 Cork, cumarone resin binder for, 137  
 —, filler, 198, 463, 933, 1275  
 —, incorporation with urea resins, 625  
 Cork masses, artificial, urea resins, 649  
 Cork meal, esterification of, 750  
 Cork substitute, cuprene, 146  
 Corncobs, furfural from, 517  
 —, reaction with phenol, 748  
 —, resins from, 526  
 Corn oil, core oil from, 821  
 —, cumarone resin varnishes with, 131  
 —, solvent, chloroprene polymerization, 157  
 —, use with chlorinated rubber, 1124, 1126  
 Corn oil acids, use in alkyl resins, 935, 967  
 Corn oil factice, preparation of, 1211  
 Corn proteins, modifiers, phenol-formaldehyde resins, 414, 416  
 Cornstarch, reaction with urea, 758  
 Corrosion, in urea manufacture, 566  
 —, of molds, 1326, 1327  
 Corundum, filler, phenol-aldehyde resin, 460  
 Cost of molding materials, 9, 23, 661, 1331, 1332  
 Cotton, fiber structure in, 64, 65, 66  
 —, digestion with alkalis, 639, 750  
 —, impregnated with Oil Stop, 1232  
 —, incorporation with aniline-formaldehyde resin, 692  
 —, —, urea resins, 639-641  
 —, reaction with phenols, 748  
 —, xerogel, 37  
 Cotton dyeing, phenol-sulphur resin in, 1191  
 Cotton flock, filler, 620, 1274, 1316  
 Cotton goods, creasing, 639  
 Cotton linters, fillers, 684, 1274  
 Cotton rags, condensation products from, 267  
 Cottonseed hulls, fillers, phenol-aldehyde molding composition, 463  
 —, reaction with phenols, 748  
 —, xylene resin from, 763  
 Cottonseed oil, chlorinated, 1127, 1155, 1221  
 —, cumarone resin varnishes from, 131  
 —, oxidized, in lacquers, 783  
 —, resins from, 1233  
 —, solvent, chloroprene polymerization, 157  
 Cottonseed oil acids, use in alkyl resins, 157, 906, 914, 945, 966, 968, 984  
 Cotton shoddy, 485  
 Cotton waste, filler, purification of resins, 338  
 Cotton wool, filler, 1126  
 Couepine acid in olive oil, 861  
 Covalence, cellulose and urea resins, 620  
 Cracked distillates, action of maleic anhydride on, 224  
 —, action of sulphuric acid on, 224  
 —, effect of light on, 230  
 —, polymerization of, 223, 225-228  
 —, reaction with formaldehyde, 213, 214  
 —, source of resins, 222-225  
 Cracked gasoline, action of electric discharge on, 231  
 —, oxidation of, 201  
 —, polymerization of, 190-193, 201, 227, 228, 231  
 —, resin from, 191, 192, 199  
 —, vapor-phase refining, 226  
 Cracked petroleum, reaction with sulphur chloride, 1178  
 —, reaction with sulphur, 1177  
 Cracked petroleum distillates, chlorination of, 1157  
 —, diluent for lacquers, 906  
 —, reaction with furfural, 527  
 Cracked-petroleum polymers, modifiers, phenol-aldehyde resins, 435  
 Cracked rosin, modifier, 400  
 Cracking, aromatic hydrocarbons, 254  
 —, copal resins, 808  
 —, olefins by, 201  
 —, petroleum oils, 221, 222  
 —, polypropylene, 259  
 —, rosin oil, 779  
 Crackle finishes, metallic soaps in, 783  
 Cracks in resins, 588  
 —, urea resins, 597, 601, 615, 620  
 —, varnish films, 19  
 Crazed effects, on resin tiles, 1243

- Crease-proof fabrics, with phenol resin, 452  
 —, with urea resin, 639  
 Cresosote, reaction with gelatin; 732, 1254  
 —, reaction with unsaturated aldehydes, 392  
 —, with phenol-aldehyde resin, 236  
 Cresosote-aldehyde resins, in sound records, 363  
 Cresosote oils, from coal tar, 360  
 —, in cold-molding compositions, 1287  
 —, in insulation, 777  
 —, reaction with copal, 810  
 —, softening agents, phenol-aldehyde resins, 423  
 —, uses of, 329, 369, 777  
 Crepe rubber in chewing gum, 1053, 1155  
 Cresidine, condensation with aldehydes, 701  
 Cresol-acetaldehyde resin, 380, 381, 421  
 Cresol-acetylene resin, 384, 385  
 Cresol-acrolein resin, 392  
 Cresol-aldehyde resins, hardening with hexamethylenetetramine, 423  
 —, optimum m-cresol content, 368  
 —, removal of excess cresol, 369  
 —, transparent, preparation, 368, 369  
 —, use of, 369, 423  
 Cresol-allyl alcohol resin, 434  
 Cresol-benzaldehyde resin, 364  
 Cresolbenzene, halogenation of, 1154  
 Cresol-castor oil, reaction with acetaldehyde, 421  
 Cresol-colophony condensation, resin from, 400  
 Cresol condensation, catalysts for, 347, 354  
 Cresol-corncob resin, 526  
 Cresol derivatives, gelatinizing agents, 718  
 Cresol ethers, resins from, 714  
 Cresol-formaldehyde reaction, catalysts for, 288, 322, 324, 420, 422  
 —, time of heating, 319, 320  
 Cresol-formaldehyde resins, acylation of, 422  
 —, alginate acid-modified, 417, 418  
 —, casein-modified, 418  
 —, chlorohydrin-modified, 429  
 —, condensation with hydroxymethyl ether, 400  
 —, glycerol-modified, 428  
 —, impregnation of paper, 643  
 —, incorporation with chloronaphthalene waxes, 1152  
 —, modified with sulphonic acids, 419  
 —, molding composition from, 367, 1288, 1289  
 —, molecular weight of, 313  
 —, production of, 318, 368  
 —, properties of, 313  
 —, solvents for, 318, 367, 423  
 —, with ester gum, 821  
 Cresol-furfural resins, 523, 526, 529-532, 643  
 Cresol-hexamethylenetetramine resins, 329  
 Cresol-paraldehyde resin, 364, 1288  
 Cresol-resin esters, preparation, 400, 800  
 m-Cresol, condensation, with benzophenone-2,4-dicarboxylic acid, 375  
 —, nature of melts of, 30  
 —, reaction with acetone, 386  
 —, — benzal chloride, 1134  
 —, — formaldehyde, 366-368, 420, 1008  
 —, — sulphuryl chloride, 935  
 —, separation from mixed cresols, 668  
 —, use of, 292, 330  
 m-Cresol-aldehyde resins, with chlorinated hydrocarbons, 423  
 m-Cresol-cyclohexanone resin, 390  
 m-Cresol-ethyl ether, action on formaldehyde, 265  
 m-Cresol-formaldehyde resins, preparation of, 367, 368  
 —, x-ray pattern of, 83  
 m-Cresol-furfural reaction, resin from, 523, 529  
 m-Cresol methyl ether, condensation, with formaldehyde, 371  
 o-Cresol, action of lead dioxide on, 271  
 —, condensation with allyl alcohol, 394  
 —, — formaldehyde, 407  
 —, curing-rate of resins from, 367  
 —, detection of, 367  
 —, nature of melts of, 30  
 —, oxidation of, 271  
 —, reacted with benzosulphuric chloride, 1135  
 —, reaction with acetone, 387  
 —, removal from creosylic acid, 359  
 —, use as disinfectant, 359  
 o-Cresol, use in modified alkyd resins, 936  
 —, use in phenol-aldehyde reaction, 368, 424  
 o-Cresol-aldehyde resin, for cold-molding, 1288  
 —, plasticizing agents, 367  
 o-Cresol-formaldehyde resin, preparation of, 367, 368  
 —, x-ray pattern of, 83  
 o-Cresol-furfural reaction, resin from, 523  
 o-Cresol-ketone-aldehyde resin, 390  
 o-Cresol-naphthalene tetrachloride condensation, 1137  
 p-Cresol, modifier for oxidized fatty acids, 1227  
 —, reaction with acetone, 386  
 —, — p-cresol-dialcohol, 304  
 —, — formaldehyde, 304, 367, 368, 378, 407, 1008  
 —, — nitrogen peroxide, 725  
 —, — phorone, 387  
 p-Cresol alcohol resin, 287  
 p-Cresol-aldehyde resins, modifiers, for phenol-aldehyde resins, 427  
 p-Cresol-dialcohol, 304, 305  
 p-Cresol-formaldehyde reaction, 304  
 p-Cresol-formaldehyde resin, oil-soluble, 368  
 —, use in alkyd resins, 936  
 p-Cresol-furfural reaction, resin from, 523  
 p-Cresol methyl ether, condensation with benzoquinone, 394  
 Cresols, action on wood pulp, 743  
 —, catalysts, condensation of aniline and formaldehyde, 695  
 —, catalysts for oxidation of, 270  
 —, chlorinated, 1154  
 —, condensation with aldehydes, 272, 287, 369, 378, 1044  
 —, — benzaldehyde, 364  
 —, — o-benzoylbenzoic acid, 376  
 —, — carbon dioxide, 374  
 —, — diphenylformamidine, 395  
 —, — lignite, 365  
 —, — paraldehyde, 364  
 —, — tiglic aldehyde and guaiacol, 280  
 —, effect on oil varnish, 408  
 —, esterification, with copals, 810  
 —, from methylcumarone polymers, 96  
 —, in creosylic acid, 359  
 —, inhibitor, polymerization of styrene, 242  
 —, isolation from coal tar, 361  
 —, in tar acid, 369  
 —, modifier, urea-aldehyde resins, 678  
 —, oxidation of, 272  
 —, oxidation inhibitor for alkyd resins, 976  
 —, phenol alcohol from, 332  
 —, plasticizer, polystyrene, 251  
 —, properties of resins from, 272  
 —, rate of condensation of, 304, 347  
 —, reaction with acetaldehyde, 380, 381  
 —, — acetylene, 383, 385  
 —, — benzaldehyde, 383  
 —, — dimethylolurea-glycerol compound, 668  
 —, — ethylene oxide, 430  
 —, — excess of formaldehyde, 324  
 —, — gaseous formaldehyde, 331  
 —, — ketones, 387, 390  
 —, — lead oxide, 273  
 —, — rosin, 799  
 —, — sulphur chloride, 1134  
 —, — tellurium chloride, 1193  
 —, — thionyl chloride, 1187  
 —, — tung oil, 402  
 —, refined, 319  
 —, removal from cresol-aldehyde resins, 369  
 —, resins with furfural, 523, 526, 529-532, 643  
 —, solvent, alkyd resins, 880  
 —, sulphonated, reaction with formaldehyde, 418  
 —, use in alkyd resins, 925, 935  
 —, use in phenol-aldehyde reaction, 423, 430  
 —, vat dye from, 1193  
 —, vinyl derivatives of, 260  
 Cresolsulphonic acid-formaldehyde resin, 421  
 Cresol-sulphur resin, 1134  
 Cresol-thionyl chloride resin, 1187  
 Cresol-urea-formaldehyde resin, 675  
 Cresotinic acids, reaction with acetaldehyde, 374  
 —, reaction with thionyl chloride, 1187

- Cresoxy fatty acids, reaction with formaldehyde, 375, 938  
 o-Cresyl benzoate, use in alkyd resin production, 925  
 --, solvent, alkyd resins, 880  
 Cresylic acid, condensation with paraldehyde, 365  
 --, constitution of, 359  
 --, hardening agent, 228  
 Cresylic acid-formaldehyde reaction, oil-soluble resins from, 408  
 Cresylic acid-formaldehyde resin, cellulose acetate modified, 433  
 --, modified, 403, 408, 559  
 --, uses of, 365, 368  
 Cresylic acid-furfural, reaction product, 536  
 Cresyl phosphates, modifiers, phenol-aldehyde resins, 432  
 Crotonaldehyde, action of ultraviolet rays on, 494  
 --, action on urea resins, 659  
 --, alcohol denaturant, 500  
 --, condensation with aniline, 700, 701, 706, 709  
 --, -- cresidine, 701  
 --, -- furfural, 521  
 --, -- naphthylamine, 696, 700, 701, 708  
 --, -- sodium aniline-ethane- $\alpha$ -sulphonate, 708  
 --, -- thiourea, 657  
 --, -- toluidine, 700, 701  
 --, formation from acetylene, 495  
 --, -- alcohol, 500  
 --, -- aldol, 489, 500  
 --, oxidation of, 500  
 --, production of, 497, 498  
 --, reaction with ammonia, 501  
 --, -- butadiene, 832  
 --, -- creosote, 392  
 --, -- myrcene, 843  
 --, -- phenols, 392  
 --, -- sodamide, 501  
 --, -- sodium vinylacetylide, 151  
 --, resinification of, 500, 501  
 --, use of, 398  
 Crotonaldehydeammonia, in rubber accelerators, 707  
 Crotonaldehyde phenylhydrazones, resin from, 501  
 Crotonaldehyde resin, 490, 492  
 Crotonaldehyde-rosin condensations, 776  
 Crotonic acid, condensation with benzaldehyde, 508  
 --, esterification of glycerol with, 1081, 1082  
 --, from crotonaldehyde, 500  
 --, incorporation in paints, 834, 976, 979  
 --, isocrotonic acid from, 1081  
 --, polymerization, 1081  
 Clotonic acid esters, polymerization, 1082  
 Crotyl cellulose, polymerization, 1081  
 Crucibles from synthetic resin, 1250  
 Crude naphtha, indene from, 99  
 Crude oil, action on acetylene polymers, 153  
 Crude phenols, resins from, 326  
 Crude rosin soap, from waste liquor, 753  
 Crude-tar oils, fractionation of, 99  
 --, oxidation with lead oxide, 273  
 Crushing strength of laminated materials, 1342  
 Cryoscopic method, applied to dimethylurea, 581  
 Crystal formation in chlorobiphenyls, 1143  
 Crystalline-finish lacquer, from sulphonamide resin, 717  
 Crystalline materials, brittleness of, 1313  
 Crystalline phase in gels, 37  
 Crystalline state, nature of, 27, 62  
 Crystalline structure of polyethylene oxides, 991  
 Crystallization from melts, 29, 30  
 Crystallization, nature of, 27  
 --, abietic acid, 765  
 --, driers, 787  
 --, rosin, 770, 771  
 --, rosin esters, 806  
 Crystallization velocity in resins, 44  
 Crystallising varnish, alkyd resins in, 978  
 Crystalloids, heating effects, 1363  
 Crystals, plasticity of, 31  
 Crystal structure, nature of x-ray pattern, 77  
 C-stage resins, resites, 295, 296, 307  
 Cubic lattice, parallel planes in, 78  
 Cumar, polystyrene varnish with, 248  
 --, resin, 123  
 Cumarilic acid, cumarone from, 93  
 Cumarone, action of sulphur on, 131  
 --, bromination of, 93  
 --, chlorinated, 138, 139  
 --, chlorohydrins from, 94  
 --, polymerization of, 92-94, 96  
 --, production of, 123  
 --, reactions of, 92, 94, 95, 131  
 --, selective polymerization of, 106  
 --, separation from indene, 99  
 --, stability of, 94  
 --, structure of, 92, 93, 518  
 --, sulphonation of, 95  
 --, synthesis of, 93-95  
 Cumarone dibromide, preparation of, 93, 94  
 Cumarone glycol, preparation of, 94  
 Cumarone-indene resins, 1257  
 Cumarone oil, cumarone resins from, 117  
 Cumarone polymerization, addition of phenols in, 118, 119  
 --, agitation during, 107, 109-111, 114, 118  
 --, automatic control of, 113  
 --, by-products in, 112, 113, 116  
 --, chlorination of naphtha used in, 109  
 --, commercial practice in, 107  
 --, continuous process for, 113, 114  
 --, control of, 109, 115, 116  
 --, diluent used in, 109, 115, 116  
 --, distillation of polymerized naphtha in, 111, 112, 120  
 --, drying of naphtha used in, 108  
 --, effect of acid concentration in, 107, 109, 110, 112  
 --, -- boiling-range of naphtha, 108  
 --, -- pressure in, 118  
 --, -- temperature on, 107, 112  
 --, neutralization of acid in, 111, 116, 117  
 --, pretreatment of naphtha, 118  
 --, purification of naphtha used in, 108, 109, 114, 115  
 --, rate of, 118  
 --, rate of sulphuric acid addition, 109  
 --, removal of bases from naphtha, 107, 108, 114, 116  
 --, -- catalyst in, 117-119  
 --, -- dark resin-forming hydrocarbons in, 108, 114, 118  
 --, -- naphthalene from naphtha, 108  
 --, -- phenols from naphtha, 107, 108, 111, 114, 116  
 --, steam distillation in, 114, 115, 118  
 --, sulphonated bodies in, 109, 111-114  
 --, temperature control in, 109, 110, 114-117, 119  
 --, use of meta-substituted aryl alkyl ethers in, 117  
 --, use of peroxides in, 115  
 --, vacuum distillation in, 118, 119  
 --, washing reaction mixture in, 107, 111, 117, 118, 120  
 Cumarone resin, action of oxygen on, 131  
 --, action of sulphur chloride on, 131  
 --, alcohol-soluble type, 119  
 --, asphalt with, 136, 138  
 --, binder for molded articles, 135, 1316  
 --, binder in cold-molding composition, 134, 1287, 1289  
 --, bloom of varnishes, 127  
 --, chicle substitute, 134  
 --, classification of, 123, 124  
 --, coal-tar resins with, 360  
 --, color of, 109, 112, 116-120, 123, 124  
 --, color test for, 1261  
 --, comparisons of dielectric constant, 134  
 --, depolymerization of, 135  
 --, destructive distillation of, 95  
 --, disinfectants, 118  
 --, dispersing agent, 136, 139  
 --, durability of films, 125  
 --, effect of temperature on, 112  
 --, effect on gelation of tung oil, 126, 1216  
 --, emulsion, 133, 138  
 --, from cumarone oil, 117  
 --, from phenol-containing naphtha, 119  
 --, from solvent naphtha, 92, 106, 107, 110, 111, 114-120  
 --, gutta-percha with, 132  
 --, hardening of, 107, 120, 1133

Cumarone resin, hydrogenation of, 119  
 —, impurities in, 125  
 —, incorporation into alkyl resins, 943  
 —, incorporation with plastic sulphur, 1216  
 —, inhibitor, gelatinization of tung oil, 1216  
 —, lacquers from, 128, 129  
 —, light-colored, 114, 115, 118, 119  
 —, light-stability of, 117, 127  
 —, metallic powder with, 135  
 —, miscibility of, 125, 128  
 —, modified, 117-119  
 —, "nail test," 124  
 —, naphthol pitch with, 135  
 —, nitrocellulose with, 823, 970, 1243  
 —, phenol-aldehyde resin with, 120, 131, 134, 135, 141, 332  
 —, plasticizers for, 120, 137  
 —, plastic materials from, 122  
 —, polystyrene with, 248  
 —, pontonak rubber with, 134  
 —, Portland cement with, 133  
 —, properties of, 106  
 —, purification of, 118  
 —, resistance to acids, 125, 130  
 —, — alkalis, 125, 137  
 —, — oxidation, 125  
 —, — water, 125, 124  
 —, removal of acidic substances from, 106, 118  
 —, — oily materials from, 106, 117  
 —, rubber softener, 132  
 —, shellac with, 135  
 —, solvents for, 106, 117, 119, 124, 125, 139, 140  
 —, spar varnish from, 127  
 —, steam distillation of crude, 117  
 —, stearin pitch with, 131  
 —, sulfonated, use of, 121, 140  
 —, sulphur with, 95, 136, 1313  
 —, tung oil with, 126, 131, 135, 137, 138  
 —, use in abrasives, 135, 986  
 —, — adhesives, 130, 133, 135, 141  
 —, — antifouling paint, 129  
 —, — bituminous paint, 132  
 —, — bronzing liquids, 129  
 —, — building compositions, 136  
 —, — cement binders, 130, 133  
 —, — cellulose ester coatings, 129  
 —, — chewing gum, 123, 134  
 —, — cloth for shoe lining, 138  
 —, — coating for pavements, 136  
 —, — coatings for electrodes, 131, 141  
 —, — coatings for molded articles, 170  
 —, — cold-molded products, 134, 1287, 1289  
 —, — electrical insulation, 118, 130, 131, 134, 136, 140, 1243  
 —, — emulsions, 139  
 —, — enamel, 129, 132  
 —, — floor-covering cement, 130, 141  
 —, — floor tile, 123, 137, 138  
 —, — floor varnish, 127  
 —, — friction tape, 132  
 —, — gaskets, 133  
 —, — indelible composition, 140  
 —, — insulating composition, 133, 135, 1243  
 —, — lacquers, 119, 133  
 —, — leather tanning, 140  
 —, — light-sensitive varnishes, 141  
 —, — linoleum, 133, 136, 137, 646, 821  
 —, — lithographic printing, 140  
 —, — magnetic cores, 135  
 —, — marking compositions, 140  
 —, — mastic flooring, 137, 138  
 —, — molding compositions, 134, 135, 140  
 —, — nail coating, 129  
 —, — oilcloth, 136, 137  
 —, — paints, 131, 133, 141  
 —, — photography, 140  
 —, — printing ink, 123, 139, 140  
 —, — rubber cement, 132, 133  
 —, — rubber compositions, 123, 131-133  
 —, — rubber varnishes, 133, 1091  
 —, — road-making composition, 136  
 —, — roofing composition, 135  
 —, — rust removers, 141  
 —, — sizing for paper, 130  
 —, — sound-insulating medium, 136

Cumarone resin, use in tin-plate coatings, 129  
 —, — transfer compositions, 140, 829  
 —, — vulcanizing flux, 132  
 —, — waterproofing compositions, 123, 130, 132, 133, 135, 138, 139  
 —, — wrinkle-finish varnishes, 128  
 —, vacuum distillation of crude, 115, 116  
 —, varnishes from, 116, 118, 120, 125-131, 135, 137  
 —, vulcanised oil with, 136  
 —, x-ray patterns of, 80, 81, 82  
 —, yellowing of oilcloth, 137  
 Cumarone resin-sulphur moldings, 136  
 Cumarone resin varnishes, formulas of, 126-128  
 —, sulphur in, 1707  
 —, yellowing of, 126  
 Cup-closing time of molding materials, 1357  
 Cuprene, applications of, 146, 147  
 —, halogenation of, 145  
 —, linoleum from, 146  
 —, oxidation of, 145  
 —, preparation of, 143-146  
 —, properties of, 144-147  
 —, reaction with benzene and sulphur, 1202  
 —, — sulphur and still-residues, 147  
 Cuprene-formation, by-products in, 145  
 Cuprene-like materials, from acetylene polymerization, 143, 144  
 —, from acetylene with benzene, 161  
 —, from benzyl alcohol, 146  
 Cuprene tar, constitution of, 145, 146  
 Cupric chloride, catalyst, preparation of dichloroethylene, 1037  
 —, —, rosin esterification, 799  
 —, metal varnish with, 449  
 —, prevention of varnish-yellowing, 1378  
 Cupric hydroxide, catalyst, phenol-formaldehyde reaction, 345  
 Cupric oxide, catalyst, acetylene polymerization, 145  
 Cupric cyanide, in anti-fouling paints, 820  
 Cuprous ammonium chloride, catalyst, acetylene polymerization, 147, 148  
 —, —, vinyl chloride preparation, 149  
 Cuprous chloride, catalyst, acetylene polymerization, 147  
 —, —, formation of chloroprene, 154  
 —, —, furfural-phenol reaction, 527  
 —, —, glycerol resinification, 504, 996  
 —, —, preparation of vinyl chloride, 1037  
 —, —, reaction of acetylene and aniline, 149, 703  
 —, —, reaction of acetylene and carbon monoxide, 161  
 —, —, complex compound with thiourea, 580  
 —, use in separation of diolefins, 184  
 Cuprous oxide, catalyst, acetylene polymerization, 144, 146  
 Curls, from urea resin, 565  
 Curing catalysts, alkyl resins, 931  
 —, urea resins, 617, 622  
 Curing of cast resins, 470  
 — isoprene polymer, 175  
 — phenol-formaldehyde-alkyl resins, 934, 936  
 — phenol resin, 320, 454, 455  
 — reactive resins, 1320  
 Curing properties of phenol-alcohol resins, 333  
 Curing-rate of phenol-aldehyde resins, 366, 367  
 Cutting oils, 121, 1200  
 Cyanamide, condensation with aldehydes, 494, 681  
 —, isourea from, 571  
 —, preparation, 681  
 —, reaction with chloral, 494  
 —, — hydrogen sulphide, 681  
 —, — mercaptans, 653  
 —, resins from, 679  
 —, trimer of, 571, 572  
 —, urea from, 568, 679  
 Cyanic acid, combination with ammonia, 569  
 Cyanides, catalysts, phenol-alcohol resins, 332  
 Cyanimide, film-hardening agents with, 633  
 Cyanonitrone, preparation of, 1140  
 Cyanogen, polymerisation, 731  
 Cyanogen bromide, reaction with n-propyl-isopropyl sulphide, 1179  
 Cyanogen chloride, reaction with aniline, 653  
 Cyanoguanidine, see Dicyanodiamide

- Cyanohydrins, preparation of, 497  
 Cyanohydrins of aldehydes, identification of, 497  
 Cyanuric acid, formation of, 570  
 —, reaction with formaldehyde, 685  
 Cyclic anhydrides, polymerization of, 998  
 —, preparation of, 997  
 Cyclic esters, formation of, 1000  
 —, steps in polymerization of, 1002  
 Cyclic hydrocarbons, dibasic acids from, 999  
 —, from diolefin polymerization, 51  
 —, solvents for phenol resins, 443  
 Cyclic ketones, reaction with carbohydrates, 701  
 —, solvents, 444  
 Cyclic structure of synthetic rubbers, 174  
 — urea resin, 571, 572, 581  
 Cyclization, polystyrene structure, 233  
 Cyclization in esterification, 863  
 Cyclization phenomenon, tung oil polymerization, 1216  
 Cyclobutadione, 553  
 1,3-Cyclohexadiene, polymerization of, 185, 188, 189  
 —, reaction with acrolein, 838  
 —, — maleic anhydride, 837  
 —, — oxygen, 189  
 —, — sulphur dioxide, 1178  
 —, — unsaturated nitriles, 850  
 —, resins from, 189  
 —, solvents for polymer of, 189  
 1,3-Cyclohexadiene polymerization, catalysts for, 189  
 Cyclohexane, condensation with monolefins, 194  
 —, crimping diene-polymer fibers with, 200  
 —, incorporation with rubber, 1092  
 —, removal of water from alkyl resins, 877  
 —, softening agent, phenol-aldehyde resins, 441  
 —, solvent, butadiene polymer, 199  
 —, —, cumarone resins, 117  
 Cyclohexane-1,2-diol, action of sulphuric acid, 1254  
 Cyclohexanol, condensation with cyclohexanone, 558  
 —, dehydrogenation, 557  
 —, fluxing agent, 337  
 —, heteropolymerization with styrene, 244  
 —, incorporation of rubber in resins, 435  
 —, modifier, phenol-formaldehyde resins, 417  
 —, oxidation to adipic acid, 891  
 —, reaction with cyclic ketones, 390  
 —, — silicon tetrachloride, 1237  
 —, softening agent, phenol-aldehyde resins, 441  
 —, solvent, 405, 680, 962  
 —, use in alkyl resins, 902, 916, 925, 938  
 —, use in castor oil-maleic compositions, 909  
 —, use of, 469  
 —, vinyl cyclohexyl ether from, 1008  
 Cyclohexanol-2-carboxylates, reaction with phenols, 391  
 Cyclohexanolicarboxylic acid, substitute for shellolac acid, 1006  
 Cyclohexanol-formaldehyde resin, preparation, 377  
 Cyclohexanol-styrene reaction, 245  
 Cyclohexanone, action on urea resins, 659  
 —, condensation of, 557, 558  
 —, condensation with aldehydes, 390, 559, 563  
 —, — enniamic aldehyde, 563  
 —, — cyclohexanol, 558  
 —, — glycerol, 560  
 —, — phenol-formaldehyde resin, 390, 559  
 —, diphenylol-1,1-cyclohexane from, 560  
 —, dodecahydrotriphenylene from, 558  
 —, molded articles treated with, 469  
 —, oxidation to adipic acid, 891  
 —, preparation of, 557  
 —, reaction with phenols, 377, 387, 389, 390, 410, 559, 560  
 —, — polyvinyl alcohol, 560, 1063  
 —, — sodamide, 558  
 —, — urea, 564  
 —, resins from, 540  
 —, solvent, alkyl resin, 989  
 —, —, chlorinated rubber hypochlorite, 1113  
 —, —, formaldehyde-glycol-monoaryl ether resins, 376  
 —, —, polystyrene, 236  
 —, swelling agent, amine-aldehyde resins, 693  
 Cyclohexanonebenzil, condensation of, 580  
 Cyclohexanone-formaldehyde resins, identification, 1258  
 Cyclohexanone-furfural, light-sensitive material from, 539  
 Cyclohexanone-phenol resin, 290  
 Cyclohexanoyl esters, modifiers, phenol-aldehyde resins, 431  
 Cyclohexene, catalyst styrene polymerization, 240  
 —, chlorinated, 1158  
 —, condensation with carbazole, 744  
 —, polymeric sulphone from, 167, 168  
 —, polymerization of, 167  
 —, reaction with sulphur dioxide, 167, 168, 1178  
 —, reaction with oxygen, 167  
 Cyclohexenone, softening agent, phenol-aldehyde resins, 441  
 Cyclohexylacetone, condensation, 560  
 Cyclohexyl acetate, solvent, chlorinated rubber hypochlorite, 1113  
 Cyclohexylamine catalyst, phenol-formaldehyde reaction, 347  
 —, constituent of shellac substitute, 1188  
 —, modifier, syntans, 420  
 Cyclohexyl amyl phthalate, plasticizer for vinyl resins, 1050  
 Cyclohexyl bromide, condensation with  $\alpha$ -naphthylhydrazine, 735  
 Cyclohexyl butyl phthalate, plasticizer for vinyl resins, 1050  
 $\alpha$ -Cyclohexyl-cyclohexanol-phenol resin, 271  
 Cyclohexyl ester of abietic acid, 800  
 Cyclohexyl esters, softening agents, phenol-aldehyde resins, 441  
 Cyclohexylethanolamine, catalyst, for phenol-formaldehyde reaction, 347  
 Cyclohexylidene-cyclohexanone, condensation, 558, 560  
 Cyclohexyl phenol, reaction with formaldehyde, 376, 411  
 Cyclohexylsilicon trichloride, formation of, 1238  
 Cyclomonooctostearic acid, formation of, 860  
 Cycloparsfins, incorporation in rubber, 1101  
 Cyclopentadecanone, oxidation, 558  
 Cyclopentadiene, gum-forming hydrocarbons, 223, 727  
 —, hydrogenation of polymers of, 186  
 —, polymerization of, 185-188, 256, 990  
 —, reactions in diene synthesis, 830, 831, 834-838, 850  
 —, reaction with p-nitrobenzene-diazonium chloride, 186  
 —, reaction with nitrogen peroxide, 727  
 —, removal from coal-tar naphtha, 114, 116  
 —, removal from crude benzol, 836  
 —, structure of lower polymers of, 186, 187  
 Cyclopentadiene polymers, depolymerization of, 186  
 —, separation of, 186  
 —, stereoisomeric forms of, 187  
 —, vulcanization of, 183  
 Cyclopentadiene rubber, structure of, 188  
 3,4-Cyclopentadienone, reaction of, 842, 843  
 Cyclopentanone, condensation with, formaldehyde, 559  
 Cyclopentenenes, chlorinated, 1158  
 Cyclopropane ester, hydrolysis, 783  
 Cyclopropene dibromide, acrolein from, 504  
 Cyclorubber, cross-linked chains in, 174  
 —, formation of, 1089  
 Cylinders, from phenolic resin molding, 464, 470  
 Cymene, from essential oils, 782, 1253  
 —, chlorination of, 1155  
 —, p-methylstyrene from, 253  
 —, resin from, 268, 269, 1253  
 Cystine from wool hydrolysis, 60

## D

- Damask effects, acetate silk and urea resins, 641  
 Dammar, binder, with phenol resins, 482  
 —, compatibility with alkyl resins, 813, 943  
 —, compatibility with chlororubber, 1119  
 —, compatibility with nitrocellulose and Anacors, 1149  
 —, esterification of, 809, 812, 814

- Dammar, hardened, 773, 776  
 —, influence on oil-solubility of phenol-aldehyde resins, 408  
 —, in lacquers, 10, 248, 632, 823  
 —, uses of, 10, 248, 408, 482, 632, 824, 913, 942  
 —, with ester gum in lacquer, 823  
 —, with polystyrene in lacquer, 248  
 —, with urea-aldehyde resins in lacquers, 632  
 Darkening of aldehyde-tar-acid varnishes, 362  
 —, of cumarone resin, 127  
 Deblooming, of lubricating oils, 230  
 Decahydronaphthalene, chlorination, 1137  
 —, diluent in polymerisation of 1,3-dienes, 182  
 —, fluxing agent, 337  
 cis-Decahydronaphthalene-2-carboxylic acid, resin from, 1253  
 Decalcomania paper, ester gum in coating for, 828  
 —, in urea resin molded products, 624  
 Decalin, drying resin from, 269  
 Decamethylene carbonate, monomer of, 870  
 Decamethylene glycol oxalate polymer, formation of, 871  
 Decamethylene phthalate, properties of, 872  
 Decarboxylation of acids, styrene from, 255, 266  
 Dechlorination, of chlorohydrocarbons, 220, 221  
 Decolorization, of coal-tar phenols, 361  
 —, of rosin, 767, 768, 769  
 Decolorizer, silica black as, 1235  
 Decomposition, of chlororubber, 1122  
 —, of glycine ethyl ester, 66  
 —, of indene picrate, 99  
 —, of rubber hydrochloride, 1112  
 —, of urea, 566  
 —, of urea-formaldehyde resin, 565, 579  
 Decomposition products, of anthracene, 268  
 —, of naphthalene, 268  
 —, of oxonides, use of, 358  
 Decoration, of fabric, use of urea resins, 625  
 —, of molded objects, 483, 484, 624, 1266, 1314, 1333  
 —, of paper, use of urea-formaldehyde resin, 685  
 Defects, in varnish films, causes of, 19  
 Degradation products, of phenol-formaldehyde resins, 292  
 —, of polyindenes, 105  
 —, of shellac, 1004  
 —, of urea resin, 579, 580, 586  
 Degreasing emulsion from pine oil derivatives, 783  
 Dehydracetic acid, from acetic acid, 552  
 Dehydration, of alcohols, 146, 254, 255, 267, 282, 994  
 —, of benzyl alcohol, 146, 267  
 —, of dibromo-p-hydroxybenzyl alcohol, 282  
 —, of glycerol, 994  
 —, of  $\beta$ -hydroxypropionic acid, 1069, 1070  
 —, of oxygenated organic compounds, 1013  
 —, of phenol-aldehyde resins, 308, 318, 329, 353, 399, 675  
 —, of phenylmethylcarbinol, 255  
 —, of resins, effect on transparency, 616  
 —, of resins, in digestors, 339  
 —, of resins, with drying oils, 340  
 —, of ricinoleic acid, 910, 1224  
 —, of saligenin, 282, 292  
 —, of sodium salicylate, 277  
 —, of urea-phenol-aldehyde resins, 675  
 Dehydrating agent, aluminum chloride, 405  
 —, calcium chloride, 405  
 —, ferric chloride, 405  
 —, for oxidation of rosin esters, 806  
 —, potassium hydroxide, 254  
 —, stannous chloride, 405, 723  
 —, sulphuric acid, 723  
 —, zinc chloride, 405, 410  
 Dehydration catalysts, for hardening alkyd resins, 981  
 Dehydrochloric acid, reaction, with animaldehyde, 509  
 —, —, with benzaldehyde, 508  
 Dehydrogenation, of ethylbenzene, styrene from, 235  
 —, of hydrocarbons, 216  
 —, of olefin polymers, 165  
 Dehydrogenation catalysts, effect on separation of styrene, 254  
 Dehydrogeranic acid, source of, 861  
 Dehydrogenic dioxide, from ngaiol, 560  
 —, reaction with oxygen, 560  
 Dehydrothioliudine, preparation of, 1196  
 Delux R. C., compatibility, with chlororubber, 1119  
 Density, determination of, 1258, 1262, 1357  
 Dentures, from acetaldehyde resins, 495  
 —, from alkyd resins, 988  
 —, from eugenol-formaldehyde resin, 375  
 —, from polystyrene resins, 250  
 —, from vinyl resins, 1048, 1259  
 —, molding of, 464, 465, 988  
 Deodorants, from cresol-acetone condensation products, 886  
 Deodorization, of naphthenic acids, 207  
 Depolymerisation, of  $\alpha$ -anhydrides, 997  
 —, of benzyl yeast-gum, 763  
 —, of cumarone resin, 125  
 —, of cyclopentadiene polymers, 186  
 —, of fossil resins, 19  
 —, of trimethylene carbonate, 870  
 —, of polyanhydrides, 997  
 —, of polyindene, 104  
 —, of polymerized aldehydes, 505  
 —, of polystyrene, 234, 236  
 Depolymerized rubber, in chewing gum, 1155  
 Derivatives of polyethylene oxides, 992, 993, 994  
 Design, of molds, 1297, 1298, 1300  
 Destructive distillation, of cumarone resins, 95  
 —, of rosin, 778  
 Desulphurization, of tung oil, 1217  
 Detection, of phthalate type resins, 957  
 Devarda's alloy, composition, 221  
 Dextrin, effect on urea-formaldehyde condensation, 616  
 —, modifier, phenol-formaldehyde resins, 414  
 —, protective colloid, for phenol-aldehyde resin, 326  
 —, reaction with organic acids, 758  
 —, —, selenium, 1168  
 Dextrose, formation of glasses from, 27  
 —, reaction with maleic anhydride, 761  
 —, —, phenols, 421, 759, 761, 762  
 —, —, phloroglucinol, 761, 762  
 —, —, phthalic anhydride, 761  
 Dextrose-phenol resins, molding, 438  
 Diacetin, modifier, phenol-aldehyde resins, 428, 429  
 —, preparation of, 995  
 —, rosin esters with, 801  
 Diacetone alcohol, condensation, by potassium hydroxide, 542  
 —, from acetone, 540  
 —, reaction with formaldehyde, 549  
 —, solvent, for chlorinated rubber, 1113  
 —, —, for nitrocellulose, 966  
 Diacetonyl sulphide, preparation, 1182  
 Diacetyl, decomposition, thermal, 552  
 —, from Grignard reaction, 1141  
 2,7-N-Diacetyldiaminodiphenic anhydride, condensation with resorcinol, 782  
 Diacetylene, formation of, 143, 162  
 —, polymerization of, 162  
 Diacetyl ester, of shellac, with acetic anhydride, 813  
 Diacetyl propane, from  $\alpha$ -isocoumarone, 1089  
 Diacetyl tartaric acid, carbon suboxide from, 1014  
 —, pyrogenic decomposition of, 1014  
 Di-alcohols, from phenol-formaldehyde reaction, 302  
 Diallyl, from acetal, 498  
 —, reaction with ammonia, 499  
 Dialdehydes, polymerization of, 507  
 Dialkoxyethyl carbonates, plasticizers, cellulose acetate, 885  
 Dialkyl esters, of itaconic acid, polymerization, 1085  
 Dialkyl ethers, formation of, 1008  
 Dialkyl oxalates, plasticizers, cellulose acetate-urea resin composition, 623  
 Dialkyl phthalates, plasticizers, cellulose acetate-urea resin composition, 623  
 —, plasticizers, vinyl halide resins, 1642

- Dialkyl tartrates, plasticizers, cellulose acetate-urea resin composition, 623
- Diallylaniline, pyrolysis of, 733
- , resins from, 733
- Diallylketene, polymerization of, 554
- Diallyl-p-phenetidine, pyrolysis of, 733
- , resins from, 733
- Dialysis, of polyvinyl alcohol, 1056
- 1,4-Diaminoanthraquinone, modifier, phenol-aldehyde resin, 442
- 2,4-Diaminodiphenylamine, reaction with 2-mercaptobenzothiazole, 705
- 2,2'-Diaminodiphenylbutane, p-isobutenylaniline from, 732
- Diaminodiphenylmethane, from aniline and formaldehyde, 690, 710
- , reaction with formaldehyde, 710
- 4,4'-Diaminodiphenylmethane, rubber age-retarder, 710
- Diaminodiphenylthiourea, from dianilinothiourea, 733
- Diaminoditolymethane, preparation of, 687
- 1,8-Diaminonaphthalene, effect of, on methyl rubber, 178
- 4,4'-Diaminotriphenylmethane, 1134
- Diamyl disulphide, preparation of, 1179
- Diamylene, co-polymerization of, with diolefins, 192
- , from tetramethylethylene, 165
- Diamyl ether, use of, in polymerization of 1,3-dienes, 183
- Diamyl phthalate, with alkyl resins, weather-resistance of, 958
- Diamyl thiomalonate, distillation of, 1014
- Dianhydride of lactic acid, structure of, 1003
- Dianilide, formation of, 998
- Dianilinothiourea, diaminodiphenylthiourea from, 733
- , reaction with hydrochloric acid, 733
- Diaphragms, acoustic, from cresol aldehyde resins, 643
- , —, from phenol-aldehyde resins, 460, 461, 643
- , —, from urea resins, 643, 649
- , —, molding of, 465
- Diarylacetal, reaction, with formaldehyde, 377
- Diarylalkylenediamines, reaction with aldol, 709
- , —, formaldehyde, 709
- Diarylamines, reaction with aldehydes, 709
- Diarylbutane, from phenoxy-p-hydroxyphenylbutane, 301
- Diarylguanidines, thioureas from, 652
- Diarylmethane, condensation with phenol alcohols, 297
- , from saligenins and phenol, 297
- Diaryl paraffins, production of, 495
- Diarylthioureas, preparation of, 652
- Diatomaceous earth, filler, 485, 1275
- , incorporation with sulphur, 1168
- Diazaminobenzene, effect on polymerization of dienes, 176, 184
- Diazamino-p-toluene, pyrolysis of, 734
- Diazo compounds, modifiers, phenol-aldehyde resins, 442
- Diazomethane, condensation with polymerized acrylonitrile, 1075
- , reactions with quinones, 832
- , use in determination of structure, 851
- Diazotisation, of aromatic amines, 1186
- Diazotised amines, condensation with p-methoxythiophenol, 1186, 1187
- , coupling with vinyl resins, 1053
- Diazotised p-nitroaniline, reaction with phenol and hexamethylenetetramine, 407
- Dibasic acids, glycol esters of, 371
- , from cyclic hydrocarbons, 999
- , from polyanhydrides, 998
- , from shellac, 1008
- , polymerisation of anhydrides of, 996
- Dibasic diglyceride, formation of, in alkyl resins, 865
- Dibenzalsuccinic acid, synthesis of, 1082
- 1,2,5,6-Dibenzanthracene, reaction with maleic anhydride, 841
- 1,2,5,6-Dibenzanthracene-9,10-endo- $\alpha,\beta$ -succinic acid, formation of, 841
- Dibenzeneulphonylarginine, esterification with butyl alcohol, 722
- , from arginine and benzenesulphonyl chloride, 722
- 2,3,10,11-Dibenzopyrene, reaction with maleic anhydride, 841
- 4,4'-Di-(hydroxymethyl)-benzophenone, effect of light on, 556
- Dibenzopyrrole, oxidation of, 744
- Dibenzoyl, condensation of, 556
- Dibenzoyl alkane, formation of, 998
- Dibenzoylperoxide, reaction with acetic acid, 556
- , action on benzene, 269
- , —, toluene, 269
- Dibenzylamine, reaction with paraformaldehyde, 707
- Dibenzylamine-formaldehyde product, rubber accelerator, 705
- Dibenzylamine hydrochlorides, styrene from chloroethylbenzene with, 252
- Dibenzylaminodiphenylmethane, from benzylaniline and formaldehyde, 699
- Dibenzylchlorosilicane, reaction with mercuric oxide, 1239
- Dibenzylidene-acetone, resinification of, 562
- Dibenzylidene-cyclohexylidene-cyclohexanone, resinification of, 560
- Dibenzylidene-stannic chloride, resinification of, 563
- Dibenzylin, plasticizer, vinyl resins, 1039, 1050
- Dibenzylketene, polymerization of, 554
- , preparation of, 552
- Dibenzylketone, 2-benzylidene-3-phenyl- $\Delta^4$ - $\beta$ -naphthopyran, 563
- , reaction with 2-naphthol-1-aldehyde, 563
- Dibenzylmalonate, carbon suboxide from, 1013
- Dibenzyl phthalate, plasticizer, 897
- Dibenzylsilicon dichloride, reaction with sodium, 1238
- 2,2'-Di-biphenyl-(ketone) dicarboxylic acid, use of, in alkyl resins, 915
- Dibromalurea, formation of, 576
- Dibromination, of diindene, 105
- , of 2-p-toluene-sulphonamidobiphenyl, 723
- Dibromanthracene, reaction with sodium disulphide, 1202
- p-Dibromobenzene, p-dibromobiphenyl from, 1141
- , treated with sodium, 1141
- Di-(bromobenzoyl)-ethanol, condensation of, 556
- Dibromobiphenyl, from dibromobenzene, 1141
- Dibromocumaron, bromocumaron from, 93
- 1,2-Dibromocyclohexane, use of, in polymerization of 1,3-dienes, 183
- Dibromodithybenzenes, divinylbenzenes from, with quinoline, 253
- 2,7-Dibromo-4,6-dinitroxanthene, reaction with piperidine, 738
- 1,1-Dibromoethylene, polymerization of, 1041, 1042
- $\alpha,\beta$ -Dibromoethyl ether,  $\alpha$ -ethoxystyrene from, 1010
- Dibromo-p-hydroxybenzyl alcohol, dehydration of, 282
- Dibromomdane, nitration of, 97
- Dibromoisoprene, decomposition of, 170
- , from isoprene tetrabromide, 170
- Dibromomalonyl bromide, dehalogenation of, 1013
- , reaction with zinc, 1013
- 1,4-Dibromo-2-methyl-2-butene, dehalogenation of, 170
- Dibromonaphthalene, reaction with magnesium, 1142
- $\alpha,\beta$ -Dibromopropionic acid, acrylic acid from, 1070
- $\alpha$ -Dibromopropionic acid,  $\alpha$ -monobromoacrylic acid from, 1079
- $\beta$ -Dibromopropionic acid,  $\beta$ -bromoacrylic acid from, 1079
- 1,2-Dibromo-ac-tetrahydronaphthalene, resin from, 1137
- $\beta,\beta$ -Dibromovinyl ether, preparation of, 1010
- Dibutylamine, use of, in preparation of drying oil from acetylene polymers, 183
- Dibutyl-2,6-endomethylene- $\Delta^4$ -phthalate, as nitro-cellulose plasticizer, 836
- Di-n-butyl ether, solvent, polyvinyl acetate, 1024

- Dibutyl oxalate, plasticizer, modified urea-aldehyde resin, 679
- Dibutyl phthalate, esterification of copal with, 810
- , plasticizer, alkyl resins, 882, 942, 962, 964, 967, 968, 968
- , chlorobiphenyl compounds, 1147
- , chlororubber, 1123
- , dihydroxybenzophenone-aldehyde resins, 374
- , intaglio printing colors, 962
- , nitrocellulose, 970
- , phenol-formaldehyde resins, 414, 445
- , polystyrene, 247
- , urea resins, 646
- , vinyl resins, 1029, 1042, 1048, 1050, 1067
- , rosin esterified with, 801
- , solvent for cellulose esters, 960
- Dibutyl tartrate, plasticizer, 378, 617, 821, 1081
- Dibutyl  $\alpha$ -terpinene-maleate, formation of, 844
- Dicarboxylates, reaction with pentaerythritol, 902
- $\alpha,\beta$ -Dicarboxylic acids, polymerization with styrene, 244
- Dichloroacetal, formation of, 1010
- Dichloroacetaldehyde, from acetylene and hydrochloric acid, 1036
- , polymerization of, 506
- Dichloroacetic acid, reaction with 1,2-ethanedithiol, 1170
- , phenol-aldehyde resins, 427
- 3,4-Dichloroacetophenone, nitration of, 725
- $\alpha$ -Dichloroacetylpyrrole, action of potassium hydride, 740
- Dichlorobenzene, plasticizer, phenol-aldehyde resins, 424, 433
- , polyvinyl chloride, 1038
- , reaction with sulphur chloride, 1200
- , sodium, 1141
- Dichlorobenzenesulphonic acid, reaction with rosin, 805
- 2,5'-Dichloro-2-benzoylbenzoic acid, reaction with phenols, 376
- Di-p-chlorobenzoyl propane, preparation, 1141
- Dichlorobiphenyl, formation of, 1143
- Dichlorobutadiene, polymerization of, 170
- , preparation of, 170
- , properties of, 170
- 2,4-Dichloro-2-butene, formation of, 154, 155
- 4-Dichlorocholesterol, formation of, 1241
- 3,5-Dichlorodimethylaniline, nitrosation of, 725
- 1',4'-Dichlorodimethylbenzene, action of alcoholic potash, 1131
- Di-chloro-di-phenyl propane, use in modified alkyl resins, 936
- Dichloro-di(cyclohexanoxy)silicon, preparation of, 1287
- $\beta,\beta'$ -Dichlorodivinylchlorarsine, preparation of, 1012
- sym-Dichloroethane, softening agent, phenol-aldehyde resins, 423
- 1,1-Dichloroethylbenzene,  $\alpha$ -chlorostyrene from, 233
- , from phosphorous pentachloride-acetophenone reaction, 233
- Dichloroethylene, condensation with aniline, 1042
- , from acetylene and hydrochloric acid, 1037
- , paint remover from, 993
- , polymerization of, 1041, 1042
- , reaction with formaldehyde, 516, 1138
- , solvent for polyvinyl acetate, 1024
- $\beta,\beta'$ -dichloroethyl ether, divinyl ethers from, 1008
- , rosin esterified with, 797
- Di-chloroethyl fumarate, resinification of, 839
- Dichlorohydrin, diglyceric alcohol from, 995
- , modifier, phenol-aldehyde resins, 439
- , reaction with metallic sulphides, 1178
- , solvent for proteins, 416
- , urea-formaldehyde resins, 619
- Dichloroindene, from indene, 96
- Dichloromethyl-diphenylmethanes, from benzyl chloride and trioxymethylene, 299
- Dichloronaphthalenes, coating compositions from, 1153
- , fluxing agent, 337
- Dichlorophenol derivatives as antiseptics, 1154
- 1,2-Dichloropropane, solvent for vinyl resins, 1053
- 1,3-Dichloro-2-propanol, preparation of, 1176
- 2,3-Dichloro-1-propanol, preparation of, 1176
- Dichloropropionic acid, acrylic acid from, 1070
- , reaction with anthracene, 840
- Dichlorostyrene, in dielectric compositions, 1151
- Dichlorourea, reaction with phenol, 1154
- Dichloroxylene, preparation of, 1154
- Dichroism, of cellulose, 63
- Dienamylidenacetone, resinification of, 562
- Dicresylin, in flooring composition, 824
- Dicresyliethane, from cresol and formaldehyde, 304
- Dioxyolpropene, preparation of, 336, 387
- Dicyanamide, polymerization, 571, 572, 731
- Dicyanodiamide, aniline from, 572
- , catalyst, phenol-aldehyde condensation, 346
- , condensation with o-amino phenol, 572
- , decomposition of, 571
- , in leaching from calcium cyanamide, 681
- , modifier, phenol-aldehyde resins, 675, 676, 680, 681
- , thiourea-aldehyde resins, 680
- , urea-aldehyde resins, 644, 680
- , reaction with formaldehyde, 644, 679, 680, 681
- , formaldehyde, catalysts, 679, 680, 681
- , hydrogen sulphide, 681
- , thioformaldehyde, 1182
- Dicyanodiamide-formaldehyde resins, modifying agents for, 680, 681
- , solvents for, 680
- , uses of, 679, 680, 681
- , with urea-thiourea-formaldehyde resins, 680
- 1',4'-Dicyanodimethylbenzene, preparation of, 1131
- Dicyclic polymers, of dimethylolurea, 581
- 1,2,3-Dicycloheptane, preparation of, 583
- Dicyclohexadiene, action of mineral acids on, 189
- Dicyclohexylacetaldehyde, semicarbazone, resinification of, 510
- Dicyclohexylethanamine, catalyst, for phenol-formaldehyde reaction, 347
- Dicyclohexylidene-cyclohexanone, from cyclohexanone, 558
- Dicyclohexyl phthalate, plasticizer, vinyl resins, 1050
- Dicyclohexylsilicon dichloride, formation of, 1238
- 2,2,2-Dicyclo-octane, synthesis of, 838
- Dicyclopentadiene, amber-like polymer of, 188
- , from coke-oven gas, 186
- , removal from naphtha, 116
- Die casting, of irregular pieces, 1296
- Dielectric materials, from Aroclors, 1150, 1151
- , from chloronaphthalene waxes, 1152
- , from styrene, 251
- Dielectric strength, of aldehyde-tar acid resins, 362
- , of alkyl-coated viscose, 965
- , of cumarone resins, 103, 134, 136
- , of cumarone-resin-sulphur moldings, 136
- , of laminated materials, 1348, 1344, 1345, 1348
- , of molded products, 22, 136, 1270, 1273
- , of molded products, determination of, 1360
- , of phenol-aldehyde resin impregnated fabric, 471
- , of phenol-formaldehyde-alkyl compositions, 934
- , of varnishes, 1372, 1373, 1375
- , tests for, 1264, 1344, 1345, 1346, 1347, 1348, 1372, 1373
- 1,4,5,8-Di-endomethylene- $\Delta^{8,9}$ -octahydroanthraquinone, formation of, 837
- Diene addition, to imino double bond, 850
- Diene reaction, estimation of isoprene through, 850
- , in determination of structures, 830
- , in stand-oil formation, 859, 860
- , rate of reaction in, 837
- , types of reaction involved in, 831
- 1,3-Dienes, see Butadiene, derivatives and homologues.
- Diene synthesis, 830
- , and structure of drying oils, 857, 858, 859, 860, 861
- , applications of, 180

- Diene system, in abietic acid, 764  
 Die pressing, of infusible phenol resin, 464  
 Dies, for extension molding, design of, 1294  
 —, types of, 1294  
 Diethanolamine, catalyst for phenol-formaldehyde reaction, 347  
 1,3-Diethoxy-3-chloromethylenepropene, 1138  
 Diethyl acetal, formation of, 495  
 —, vinyl ethyl ether from, 1007  
 Diethylamine, catalyst, for cresol condensation, 347  
 —, effect on polymerization of phenylacetylene, 162  
 —, reaction with  $\alpha$ -anhydrides, 998  
 —, — furfural, 703  
 —, — 2-hydroxy-3-carbethoxy-4-pentanone, 546  
 —, — 2-methyl-3-ketobutanol in presence of formaldehyde, 543  
 —, — paraformaldehyde, 707  
 Diethylamine-modified phenol-aldehyde resin, use in dyeing, 425, 426  
 Diethylaminoethyloleamide, emulsifying agent, 180, 245, 246  
 —, as polymerization catalyst, 193  
 Diethylaniline, reaction with chloroketones, 549  
 —, — phosphorous trichloride, 689  
 Diethylbenzene, styrene homologues from, 254  
 Diethyl disulphide, preparation of, 1170  
 Diethylene glycol, reaction with boric acid and borax, 893  
 —, — carbohydrates, 761  
 —, — malic acid, 888  
 —, — rosin esters of, 796  
 —, use in alkyd resins, 998, 907, 914, 968  
 —, —, alkyd-resin pamph, 984  
 —, — softener for cellulose ester adhesives, 989  
 Diethylene glycol carbonate, properties of, 872  
 Diethylene glycol monobutyl ether, esterification of, rosin with, 796  
 Diethylene glycol phthalate, properties of, 864  
 —, use in coating wire, 986  
 Diethylene glycol succinate, with nitrocellulose, 907  
 Diethyl ether, use in polymerization of 1,3-dienes, 183  
 Diethyl itaconate, polymerization of, 1035  
 Diethylketene, polymerization of, 554  
 —, preparation of, 552  
 Diethyl ketone, pyrolysis of, 551  
 —, reaction with diphenylpropane, 389  
 —, — formaldehyde, 547  
 —, — furfural, 537  
 Diethylmalonate, reaction with phosphorus pentoxide, 1013  
 p-Diethylolbenzene, p-divinylbenzene from, 254  
 Diethyl oxalate, plasticizer, urea-aldehyde resins, 617, 679  
 —, solvent, for alkyd resins, 879  
 Diethyl pentasulphide, preparation of, 1170  
 Diethyl phthalate, esterification of colophony with, 801  
 —, in adhesive for laminated glass, 676  
 —, modifier, alkyd resins, 430  
 —, modifier, phenol-aldehyde resins, 430  
 —, plasticizer, alkyd resins, 852, 913  
 —, —, chlororubber, 1123  
 —, —, phenol-aldehyde resins, 447  
 —, —, urea resins, 998  
 —, —, vinyl resins, 1050  
 —, solvent, for alkyd resins, 879  
 Diethyl sulphate, incorporation with rubber, 1098  
 Diethyl tartrate, plasticizer, phenol-aldehyde resins, 878  
 —, plasticizer, urea resins, 617  
 Diethyl thiomalonate, distillation of, 1014  
 4,4'-Diethylureidobiphenyl, nitration of, 725  
 Differential rolls, uses of, 1279  
 Diffusion, determination of molecular weights by, 67  
 Difluoroethylene, stability of, 1042  
 Difurylbutadiene, stability of, 170  
 Digestion, of wood, 947, 949  
 Digestor, use in preparation of phenol-aldehyde resins, 823, 878, 894, 895, 896  
 Diglyceric alcohol, diocten from, 995  
 —, from dichlorohydrin, 995  
 Diglyceride oils, formation of, 938, 951  
 Diglycerol, preparation of, 994, 995, 996  
 —, properties of, 992  
 —, solubility of, 995  
 Diglycerol tetra-acetate, preparation of, 995  
 Diglycerol tricarboxylate, preparation of, 885  
 Diglyceryl triphthalate, from phthalic anhydride and glycerol, 876  
 Diglycolic acid, catalyst, for rosin esterification, 795  
 —, reaction with cellulose, 904  
 —, — glycerol, 894  
 —, use in alkyd resins, 883  
 Diglycolic anhydride, use in alkyd resins, 929  
 Diglycolic diamide, reaction with formaldehyde, 685  
 Dihaloethanes, vinyl halides from, 1035  
 Dihydroacrylic acid, preparation of, 883  
 —, reaction with cellulose, 904  
 Dihydric alcohol esters of drying oils, nature of drying of, 920  
 Dihydrocumarone, from cumarone dibromide, 94  
 —, from cumarone resin, 95  
 Dihydrodesoxycinchonine, resinification, 745  
 Dihydrogen phosphates, catalysts for phenol-formaldehyde reaction, 353  
 $\gamma$ -3-Dihydroindolylbutyric acid, benzoylation, 743  
 $\beta$ -3-Dihydroindolylpropionic acid, reaction with benzoyl chloride, 743  
 Dihydronaphthalene, reacted with alkyl halides, 1132  
 Dihydrophenanthrene, from phenanthrene, 268  
 1,8-Dihydropyriminazole, nature of formation of, 850  
 Dihydroxyabietic acid, modifier, acetaldehyde resin, 492  
 —, reaction with rosin, 803  
 Dihydroxyacetone, polymerization of, 542  
 —, reaction with phenols, 393  
 —, x-ray pattern of, 50  
 Dihydroxyarylmethanes, as resin intermediates, 302  
 Dihydroxybehenic acid, use in alkyd resins, 910  
 Dihydroxybenzophenone, preparation of, 374  
 —, reaction with aldehydes, 372, 374, 557  
 Dihydroxybenzophenone-aldehyde resins, adhesive from, 373, 374  
 —, modifiers for, 374  
 1,1-Dihydroxyvelopropene, polymerization of, 558  
 Dihydroxydibenzylamines, from phenol and formaldehyde, 309  
 $\beta$ , $\beta$ -Dihydroxydinaphthylmethane, reduction of, 270  
 —, resin from, 270  
 Dihydroxydiphenyl, condensation with resins, 408  
 —, effect, conversion of resins, 340  
 2,2'-Dihydroxydiphenylamine, preparation of, 1190  
 a,a',-p,p',-Dihydroxydiphenylbutane, from phenol and n-butylaldehyde, 301  
 4,4'-Dihydroxydiphenyldihydorrubber, methylation of, 1114  
 —, preparation of, 1114  
 —, solvents for, 1114  
 Dihydroxydiphenyldimethylmethane, preparation of, 386, 388  
 —, reaction with acetone, 386  
 —, — formaldehyde, 386  
 Dihydroxydiphenylmethane, preparation of, 382, 383  
 —, reaction with hexamethylenetetramine, 382  
 —, reaction with paraformaldehyde, 382  
 Dihydroxydiphenylmethane, preparation of, 294, 297, 300, 306  
 —, reaction with phenol alcohols, 287, 288  
 —, resin from, 306, 322  
 —, use in alkyd resins, 915  
 Dihydroxydiphenylmethane dicarboxylic acid, modifier, esterified rosin, 805  
 —, reaction with monobasic acid and glycerol, 374  
 Dihydroxydiphenylpropane, phenol alcohol from, 333  
 4,4'-Dihydroxy- $\beta$ , $\beta'$ -diphenylpropane-formaldehyde-amine resins, as rubber anti-agars, 377  
 o,o'-Dihydroxydiphenyl sulphide, formation of, 1159  
 Dihydroxyditolyethane, preparation of, 380

- 4,5-Dihydroxy-cis-3,6-endomethylene hexahydro-phthalic acid, dilactone from, 836, 837
- Di- $\beta$ -hydroxyethyl sebacate, from ethylene glycol and sebacic acid, 898
- Di- $\beta$ -hydroxyethyl succinate, from succinic acid and glycol, 887
- 1,3-Dihydroxy-5-hexanone, condensation of, 542
- , methylation of, 542
- 1,2-Dihydroxyindane, from indene, 98
- Dihydroxyisopropylphenylthale dicarboxylic acid, shellolic acid, 1005
- Dihydroxymethane, monoacetate of, use of, 343
- Dihydroxymethylenebensidine, from formaldehyde and bensidine, 688
- Dihydroxymethylxanthene, preparation of, 333
- 2,2'-Dihydroxy-1-naphthylidene-1'-naphthylmethyl-amine, from  $\beta$ -naphthol and hexamethylene-tetramine, 308
- 5,8-Dihydroxy-1,4-naphthoquinone, reaction with butadiene, 884
- Dihydroxypalmitic acid, copal esterified with, 810
- 1,3-Dihydroxypropylidene-glycerol, non-polymerization of, 503
- Dihydroxystearic acid, chlorination of, 1220
- , estolides from, 1222
- , from zinc chloride and oleic acid, 1222
- , modifying agent for acetaldehyde resin, 492
- , reaction with pentaerythritol, 901
- , — rosin, 803
- , use in alkyl resins, 910, 914
- , vacuum distillation of, 1222
- 2,4-Dihydroxystyrene, from resorcinol and acetylene, 256
- 1,4-Dihydroxy- $\Delta^4$ -tetrahydroanthraquinone, formation of, 884
- Dihydroxytriphenylcarbinol, preparation of, 1135
- Dihydroxytriphenylmethane, preparation of, 1134
- Dihydroxyundecic acid, aleuritic acid, 1004
- Diindene, from indene, 101
- , from polyindene, 104
- ,  $\alpha$ -hydrindone from, 105
- , isolation of, 103
- , oxidation of, 105
- , properties of, 105
- Diindole hydrochloride, preparation of, 743
- , reaction with indole, 743
- Diiodobiphenyl, reaction with copper, 1142
- 1,2-Diiodoethane, vinyl iodide from, 1035
- Di-iodohydroxydiphenyl sulphide, preparation of, 1166
- Diiodomethylidiphenylmethanes, polymerization of, 299
- Diisomylpyridilium iodide, resinification of, 737
- Diisobutylene, catalyst, 2,3-dimethylbutadiene polymerization, 176
- , —, furyl alcohol polymerization, 522
- , —, indene polymerization, 103
- , —, styrene polymerization, 176, 240
- , from isobutylene, 167
- Diisobutyl ether, use in polymerization of 1,3-dienes, 183
- Diisopropylcarbazole, reaction with formaldehyde, 744
- , — rosin, 805
- Diisopropylphenylthale sulphonic acid, ammonium salt, use in alkyl resin emulsions, 948
- $\alpha,\beta$ -Di-isoxazole ketone, effect of sunlight, 737
- , from nitric acid and acetylene, 737
- Diketones, reaction with isoureas, 571
- Diketotetraabenzylcyclobutane, from dibenzylketene, 584
- Diketotetrahydrothiasolés, from thiocarbaniide, 575
- , reaction with aromatic aldehydes, 575
- Dilactic acid, reaction with cellulose, 904
- Dilactone form of 4,5-dihydroxy-cis-3,6-endomethylenehexahydrophthalic acid, 836, 837
- Dilvallic acid, from pyrrole and maleic anhydride, 847
- , from pyrrole-2,5-dipropionic acid, 845
- Diluents, in polymerizations, 109, 116, 118, 181, 182, 183, 185, 186, 802
- "Dimedon", reactions of, 497
- 3-Dimensional pattern, in alkyl resins, 863
- Dimeric acid, formation of, 1002
- Dimeric ketene, from acetic acid, 552
- Dimeric trimethylenglycol oxalate, formation of, 871.
- Dimerization, of indene, 102
- , of asym-diphenylethylene, 233, 234
- , of  $\alpha$ -methylstyrene, 233, 234
- Dimers, of acetylene, 147
- , of asym-diphenylethylene, 259
- , of atropic acid, 1084
- , of isoeugenol, chlorination of, 1154
- , of phenylated butadienes, 170
- 3,4-Dimethoxybenzaldehyde, polymerization of, 509
- Di-( $\beta$ -methoxyethyl) phthalate, plasticiser, 897
- 3,4-Dimethoxystyryl methyl ketone, resinification with piperidine, 568
- Dimethylamine, catalyst, ethylene oxide polymerization, 992
- , effect on polymerization of phenylacetylene, 162
- , reaction with 2-methyl-3-ketobutanol in presence of formaldehyde, 543
- , — phenol and formaldehyde, 310
- Dimethylamine hydrochloride, catalyst, acetone-formaldehyde reaction, 857
- , reaction with phloroglucinol and formaldehyde, 310
- p-Dimethylaminobenzaldehyde, reaction with aldehydes, 509
- 8-(2-Dimethylaminocyclohexylamino)-6-methoxy-quinoline, resinification of, 739
- bis-Dimethylaminophenyl sulphides, preparation, 1194
- $\omega$ -Dimethylaminopropiophenone hydrochloride, from acetophenone and formaldehyde, 557
- , reaction with water, 557
- Dimethylaniline, catalyst, phenolic resins, 347
- , —, polyvinyl-alcohol alkylation, 1080
- , reaction with benzaldehyde, 699
- , — boron triphenyl, 1241
- , — formaldehyde, 687
- , —  $\beta$ -ethoxy-acrolein-acetal, 690
- Dimethylbenzoyl bromide, bromination of, 1156
- Dimethylbenzyl chloride, reaction with hydrocarbons, 1132
- , — phenol, 1133
- , — rosin esters with, 799
- Dimethylbutadiene polymer, use of, 198
- 1,1-Dimethylbutadiene, polymerization of, 169
- 1,2-Dimethylbutadiene, polymerization of, 169
- 1,3-Dimethylbutadiene, polymerization of, 179, 180, 181
- 1,4-Dimethylbutadiene, polymerization of, 169
- 2,3-Dimethylbutadiene, polymerization of, 49, 169, 172, 173, 175, 176, 177, 179, 180, 181, 182, 183
- , —, catalysts for, 169, 172, 173, 175, 176, 177, 179, 180, 181, 182, 183
- , —, in aqueous emulsions, 179, 180, 181
- , —, see also Butadiene homologues.
- , reaction with benzoquinone, 833
- , — sulphur monochloride, 1179
- , rubber from, 172, 174, 175, 177, 179, 180
- , synthesis from acetylene, 177
- Dimethylbutadienes, characterization of, by diene reaction, 830
- , co-polymerization with styrene, 251
- , polymerization of, x-ray studies, 50
- , reaction with aromatic hydrocarbons, 194
- 3,5-Dimethyl-4-carbomethoxy-pyrrol-2-acrylic acid, polymerization of, 1084
- Dimethylcumarones, from coal tar, 96
- 3,4-Dimethylcyclobutanamine, from oxime of 2-methyl-3-ketobutanol, 543
- 2,6-Dimethyl-1,5-cyclo-octadiene, rubber from, 1088
- trans-1,2-Dimethylcyclopropane-1,2-dicarboxylic acid, reaction with acetyl chloride, 989
- 9,10-Dimethylidihydroanthracene resin, 258
- Dimethylidihydro- $\Delta^{1,4}$  phthalate, dehydrogenation of, 884
- , preparation of, 834
- Dimethylidihydroresorcinol, reaction with acetaldehyde, 497
- , — aldols, 497

- Dimethyl-3,6-endomethylene-3,6-dihydrophthalate, reduction of, 837, 838  
 —, formation of, 837, 838  
 Dimethylenemethylol-tri-o-toluenesulphonamide, from arylmonosulphonamide resin, 715  
 Dimethyleneurea, bromine addition product of, 579  
 —, formation of, 587  
 —, polymerization of, 587  
 Dimethyl ether, in polymerization of 1,3-dienes, 183  
 —, of pyrogallol, use, 821  
 1,3,5-Dimethylethylbenzene, 3,5-dimethylstyrene from, 253  
 2,5-Dimethyl furan and maleic anhydride, reaction of, 847  
 Dimethylglycidol, use, with chlororubber, 1111  
 1,2-Dimethylglyoxaline, reaction with methyl acetylenedicarboxylate, 849  
 Dimethylhexen-diol, reaction with hydrogen bromide, 1168  
 1,2-Dimethylindole, reaction with maleic anhydride, 849  
 Dimethylisoprene, reaction with ethyl  $\alpha$ -carboxylate, 831  
 Dimethylketene, preparation of, 552  
 —, reaction with aniline, 554  
 —, — arylcarbimides, 555  
 —, — carbon disulphide, 553  
 —, — carbon oxysulphide, 553  
 —, — isocyanates, 553  
 —, — ozone, 554  
 —, — trimethylamine, 554  
 Dimethyl ketone, action on pectose, 763  
 Dimethylmalonate, carbon suboxide from, 1013  
 3,6-Dimethyl-2,4-octadiene-1,8-disulphonic acid, potassium salt of, formation of, 172  
 —, —, polymerization of, 172  
 Dimethylol acetone, unsaturated keto-alcohol from, 544  
 2,6-Dimethylol-p-cresol, for p-cresol-formaldehyde reaction, 293  
 Dimethyloldimethylmethane, alkyd resins from, 904  
 2,6-Dimethylol-4-methylphenol, see p-Cresol-dialcohol.  
 Dimethyloltetrahydro-4-pyrone, preparation of, 545  
 Dimethylolthiourea, coating composition from, 637  
 —, reaction with cuprous chloride, 581  
 Dimethylolurea, action of acids on, 577, 609  
 —, action of alkalis on, 577, 638  
 —, coating composition from, 637  
 —, condensation of, 581, 582, 583, 584, 586, 637  
 —, —, to Goldschmidt's compound, 581, 583  
 —, decomposition of, 577  
 —, formation of, 574, 577, 579, 586, 592, 593  
 —, modifier, phenol-furfural resin, 672  
 —, —, phenol-sulphur chloride resins, 672  
 —, polymerization of, 581, 609, 610  
 —, polymerization, buffers, 614  
 —, properties of, 577, 581, 592  
 —, reaction with adipic 1,1'-di-glyceride, 668  
 —, — benzene derivatives, 574  
 —, — casein, 679  
 —, — ethylene chlorohydrin, 667  
 —, — glycerol, 668, 669  
 —, — hydroxyesters, 646  
 —, — o-nitrophenol, 574  
 —, — Tollens reagent, 592  
 —, resins from, 635  
 —, straight chain polymers of, 581  
 —, use of, in urea-formaldehyde-alkyd emulsification composition, 948  
 Dimethylolurea-adipic 1,1'-diglyceride compound, benzoylation of, 668  
 Dimethylolurea-ethylene chlorohydrin compound, reaction with sodium salt of linseed oil acids, 667, 668  
 Dimethylolurea-glycerol compound, plasticiser, 669  
 —, reaction with cresol, 668  
 Dimethylolurea peroxide, formation of, 586  
 Dimethyloxalate, reaction with polyhydric alcohols, 885  
 2,4-Dimethylphenol, from coal tar, 361  
 2,6-Dimethylphenol, dioxynolmethane from, 301  
 —, Novolak from, 301  
 Dimethyl phthalate, reaction with colophony, 801  
 Dimethylpyrogallol, reaction with tiglic aldehyde, 280  
 Dimethylpyrone, reaction with hydrazine hydrate, 735  
 2,4-Dimethylpyrrole, reaction with benzaldehyde, 741  
 —, — citraconic anhydride, 848  
 —, — methylacetylene dicarboxylate, 848  
 —, — p-nitrobenzaldehyde, 741  
 Dimethylquinol, reaction with aniline, 702  
 2,4-Dimethylstyrene, polymerization of, 259  
 3,5-Dimethylstyrene, preparation of, 253  
 Dimethylsulphonamide, reaction with formaldehyde, 716  
 2,3-Dimethylthiophene, from ebonite, 1089  
 Dimethyl-p-toluidine, from formaldehyde and p-toluidine, 687  
 2,4-Dimethyl-3-vinylpyrrol-5-carboxylic acid, re-sinification of, 241  
 Di- $\beta$ -naphthol, bromination of, 1154  
 Dinaphthopyran, from  $\beta$ -naphthol and formaldehyde, 295  
 ms-[4-nitrophenyl]-Dinaphthopyran, preparation of, 295  
 Dinaphthylamine, reaction with aldol, 709  
 —, — butylaldehyde, 709  
 —, — formaldehyde, 709  
 Di- $\beta$ -naphthylamine, reaction with sulphur dichloride, 1194  
 2,2'-Dinaphthyl-1,1'-dicarboxylic acid, use of, in alkyd resins, 915  
 Dinitroabietic acid, 731  
 p-Dinitroamino-benzaldehyde, reaction with 4,6-dinitro-m-xylene, 726  
 2,4-Dinitrobenzaldehyde, reaction with benzyl chloride, 509  
 Dinitrobenzene, fluorinated, 1157  
 —, oxidation of, 725  
 —, plasticizer, alkyd resins, 882, 890  
 —, — phenol-aldehyde resins, 440  
 —, — resins from, 725, 726  
 2,4'-Dinitrophenyl, reduction, resins from, 726  
 Dinitrochlorobenzene, toxic constituent in coating composition, 154  
 Dinitrophenol, condensation with diphenylcarbamide chloride, 727  
 $\beta$ -2,4-Dinitrophenylhydroxylamine, resins from, 733  
 Dinitrotoluene, combination with polyvinyl chloride, 1044  
 4,6-Dinitro-m-xylene, condensation with aldehydes, 509, 726  
 —, resinification of, 509  
 Diolefin polymers, nature of, 51  
 Diolefins, by cracking, 221  
 —, condensation with aromatics, 193, 194, 225  
 —, —, catalysts, 193, 194  
 —, co-polymerization with monoolefins, 189, 190, 191, 192, 193  
 —, —, catalysts, 189, 190, 191, 192, 193, 194  
 —, estimation of, by diene reaction, 830  
 —, gum-forming hydrocarbons, 224  
 —, polymerization of, 49, 51, 164, 165, 168, 169, 174, 175, 176, 179, 185, 225, 226, 227, 228  
 —, —, in aqueous emulsion, 175  
 —, —, mechanism of, 49  
 —, —, with glyceride oils, 1228  
 —, polymerised, with urea resins in coatings, 687  
 —, reaction with formaldehyde, 212  
 —, — methyl-methylene ketones, 550  
 —, separation of, from monoolefins, 165, 184  
 Dioxane, by-product, in preparation of divinyl ether, 1008  
 —, catalyst, in chloroprene polymerization, 156  
 —, preparation of, 993, 1253, 1254  
 —, solvent for polyvinyl acetate, 1026  
 —, use of, 182, 183, 469  
 Dipentaerythritol, from formaldehyde and acetaldehyde, 901  
 Dipentane, solvent for alkyd resins, 973  
 Dipentene, co-polymerisation, with monoolefins, 192  
 —, emulsions, in tanning, 1247  
 —, formation of, 1087  
 —, from distillation of rubber, 1089  
 —, from isoprene, 173  
 —, from linseed oil, 733  
 —, from wood, 780

- Dipentene, reaction with benzene, 184  
 —, — maleic anhydride, 845  
 —, rubber-like material from, 1247  
 —, use in crimping fibers of diene polymers, 200  
 N,N'-Diphenacyl- $\alpha$ -pyridone imide, resinification of, 738  
 Diphenic acid, dihydrazide of, resins from, 736  
 —, from phenanthrene, 269  
 —, modifier, phenol-aldehyde resins, 439  
 —, reaction with polyhydroxy acids, 910  
 —, use in alkyd resins, 883  
 Diphenic anhydride, reaction with resorcinol, 391  
 Diphenylacetylene, see Tolane  
 Diphenylacetylphthalimide, decomposition of, 553  
 Diphenylamine, hardening agent for shellac, 1287  
 —, plasticizer, phenol-aldehyde resins, 424  
 —, polymerisation inhibitor, 1080  
 —, reaction with aldehydes, 690, 695, 709  
 —, — d-glutamic acid, 690, 732  
 —, — sulphur dichloride, 1194  
 —, use in alkyd resins, 922  
 —, use in flooring composition, 984  
 —, use with chlororubber, 1111  
 Diphenylaminocyclobutane carboxylic acid, lactone from, 1141  
 Diphenylbutadiene, reaction with acyl chlorides, 1138  
 1,4-Diphenylbutadiene, from polypropylbenzene, 259  
 Diphenylbutyndiol, action of hydrogen bromide on, 1158  
 Diphenylcarbamide chloride, reaction with nitrophenols, 727  
 Diphenylcarbodiimide, reaction with aniline, 573  
 —, resins from, 573, 684  
 Diphenyl carbonate, reaction with glycerol, 885  
 —, — hexamethylenetetramine, 377  
 Diphenylchloromethane, reaction with ethyl alcohol, 1158  
 —, resins from, 1132  
 4,5-Diphenylcyclopentenolone, reaction with tolane, 163  
 Diphenyldiaminodibenzylmethane, 699  
 6,6'-Diphenyldiazoethane, resin from, 734  
 Diphenyldichlorosilicane, reaction with mercuric oxide, 1239  
 Diphenyl disulphide, formation of, 1201  
 bis-Diphenylene ethylene, preparation of, 1140, 1141  
 —, triphenylene-cyclohexane from, 259, 260  
 Diphenyleneketone-4-carboxylic acid, 391  
 Diphenylene oxide, as film strengthener, in oils, 1158  
 asym-Diphenylethane, from benzene and vinyl chloride, 1045  
 —, resin from, 256  
 Diphenyl ether, action on formaldehyde, 265  
 —, benzene from, 270  
 —, phenol from, 270  
 —, resin from, 270, 1253  
 asym-Diphenylethylene, catalyst, styrene polymerisation, 240  
 —, oxidation of, 259  
 —, polymerisation of, 233, 234, 259  
 —, reaction with maleic anhydride, 854, 855  
 —, 1,1,2,3-tetraphenyl-1-butene from, 259  
 —, 1,1,3-triphenyl-3-methylvinylidene from, 259  
 sym-Diphenylethylene, reaction with maleic acid, 163  
 Diphenylethylenediamine, reaction with aldehydes, 709  
 Diphenylformamidine, reaction with cresols, 395  
 —, — guaiacol, 395  
 —, — naphthols, 395  
 —, — pyrogallol, 395  
 —, — resorcinol, 394  
 Diphenyl-furylmethane, gum from, 519  
 Diphenylguanidine, anti-aging agent in varnishes, 831  
 —, from aniline and cyanogen chloride, 633  
 —, hardening agent, shellac, 702  
 —, in vulcanizing synthetic rubber, 195, 198, 200  
 —, plasticizer, olefin-polysulphide resins, 1174  
 —, reaction with aldol, 703  
 —, — furfural, 708  
 Diphenylguanidine, removal of acid by, 1024  
 Diphenylisothiohydantoin, from thiocarbamilide, 575  
 Diphenylketene, reactions with methylethyl malonic acid, 552  
 Diphenylmalonate, carbon suboxide from, 1013  
 —, from benzyl chloride, 1131  
 —, from phenol and formaldehyde, 304  
 —, plasticizer, polyvinyl chloride, 1038  
 p,p'-bis-Diphenylmethane, resin from, 270  
 Diphenylmethane dialcohol, polymer of, 299  
 Diphenylmethyl ethyl ether, resinification of, 1158  
 2,6-Diphenyl-4-methylpyrillium, reaction with  $\gamma$ -methylenepyrrol, 561  
 2,6-Diphenyl-4-methylpyrillium perchlorate, from acetophenone, 560  
 —,  $\gamma$ -methylenepyrrol from, 561  
 Diphenyl- $\alpha$ -naphthyl carbinol, preparation of, 1141  
 Diphenyl- $\alpha$ -naphthylchloromethane, reaction with mercuric oxide, 1141  
 1,8-Diphenyl-1,3,5,7-octatetraene, reaction with maleic anhydride, 854  
 Diphenylcyclohexane, plasticizer, vinyl resins, 1050  
 —, preparation of, 389  
 —, reaction with formaldehyde, 377  
 Diphenylol-1,1-cyclohexane, from cyclohexanone and phenol, 560  
 1,10-Diphenyl-1,3,5,7,9-decapentaene, reaction with maleic anhydride, 854  
 p-Diphenylol-dimethylmethane, preparation of, 386  
 Diphenylolethane, from phenol-acetaldehyde reaction, 294  
 —, homologues of, 294  
 Diphenylolethane, from phenol alcohols and phenol, 297  
 —, from reaction of phenol and formaldehyde, 294, 297, 299  
 —, polymerization of, 299  
 —, properties of, 295  
 —, reaction with paraformaldehyde, 297  
 —, see Dihydroxydiphenylmethane  
 Diphenylolethane alcohols, from phenol alcohols, 297  
 Diphenylolethane derivatives, from reaction of phenol and formaldehyde, 292, 294  
 Diphenylpropane, catalysts, preparation of, 386, 388, 389  
 —, plasticizer, 717, 720, 1050  
 —, reaction with acetylene, 386  
 —, — aldehydes, 299, 300, 388, 389  
 —, — ketones, 389  
 Diphenylpropane-formaldehyde resin, in lacquers, 390, 1027  
 —, in waterproofing composition, 433  
 Diphenylpropane-tetracarbinol, reaction with ethylenedichlorohydrin, 429  
 Diphenyl orophthalate with nitrocellulose, 971  
 Diphenyl oxide, alkyl halides from, 1132  
 —, removal of water by, urea-formaldehyde resins, 601  
 sym-Diphenyl-p-phenylenediamine, reaction with aldehydes, 709  
 Diphenylphthalate, plasticizer, 246, 247  
 Diphenylpropane, from polystyrene, 232  
 —, oxidation of, 510  
 —, plasticizer for polystyrene, 251  
 Diphenylsilicon dichloride, action of sodium on, 1287  
 Diphenyl sulphide, formation of, 1201  
 Diphenylthiourea, from aniline and carbon disulphide, 652  
 —, reaction with formaldehyde, 658  
 Diphenylthiourea hydrobromide, catalyst, in formation of metaldehyde, 489  
 Diphenyl-p-tolylselenonium chloride, organic glass from, 1241  
 Diphenyltolylsilicanediol, reaction with potassium hydroxide, 1238  
 Diprene, from isoprene, 172  
 Dipropargyl, from acetylene polymerisation, 143  
 —, polymerisation of, 163  
 Dipropargyl methylene ether, reaction with ethyl magnesium iodide, 1254  
 Dipropylamine, catalyst, cresol condensation, 347

- Dipropylketene, polymerization of, 554  
 --, preparation of, 552  
 N,N'-Dipyrrolidinomethane, resinification, 741  
 Diricinoleic acid, esterification with sulphuric acid, 1224  
 --, preparation of, 1224  
 Dirt, prevention, in molds, 607, 608  
 Disacryl, from acrolein, 501, 502  
 --, reaction with urea, 671  
 Disalicylic anhydride, preparation of, 375  
 Discoloration, of chlorinated rubber, 1111  
 --, of moldings, prevention of, 1326, 1328  
 --, of resins, 112, 331, 1148  
 --, --, tests for, 1378  
 Disilicic ester, structure and formation of, 1236  
 Disinfectants, from o-cresol, 359  
 --, from cresol-acetone condensation products, 386  
 --, from modified cumarone resins, 118  
 --, from phenol-aldehyde resins, 289  
 --, from tar acids, 366  
 Disk mold test, for molding materials, 1358  
 Disk records, from horn-filled resin, 1249  
 Disks, from urea-formaldehyde resins, 605  
 Disodium phosphate, catalyst, condensation, aldehydes and ketones, 546  
 --, hardening agent, urea-formaldehyde resins, 597  
 --, neutralizing agent, urea-formaldehyde condensation, 647  
 Disodium tartrate, reaction with 2-chloropropene, 1045  
 Dispersing agent, benzoin condensation products, 268  
 --, 1-chloronaphthalene-formaldehyde resin, 266  
 --, cumarone resin, 136  
 --, from naphthenic acids, 207  
 --, from tall oil, 756  
 --, in matt-varnishes, 788  
 --,  $\beta$ -naphthalene sulphonic acid condensation products, 263  
 --, polyacrylates, 1705  
 --, polymers of ethylene oxide, 993  
 --, polyvinyl alcohol, 1037  
 --, sodium polyacrylate, 1072  
 --, synthetic resins, 1250  
 Dispersing media, from polymeric itaconic acid with vinyl compound polymers, 1086  
 Dispersion, of alkyl resin, in acetone, 961  
 --, in aqueous alkali, 945  
 --, of ester gum in reclaimed rubber, 827  
 --, of gels, 39  
 Dispersoids, protective colloid for, polyvinyl alcohol, 1036  
 Dissociation, of aromatic hydrocarbons, 268  
 Distillation, destructive, of castor oil, 927  
 --, of rosin, 778  
 --, of castor oil, 927  
 --, of crude cumarone resin, 111, 112, 115, 117, 118, 119

 —, from cuprene, 146  
 —, for dielectric strength tests, 1372  
 —, requirements for, in testing, 1345, 1347  
 Electrolysis, of phenol solutions, 272  
 —, of salicylic acid, 277  
 —, of *m*-xylene, 272  
 Electrolytes, acceleration of gelatinisation, 597  
 —, isocolloid materials with fatty acids in, 1227  
 Electrolytic cells, sheets for, from synthetic rubber, 200  
 Electrolytic hydrogenation, of sulphite liquor resins, 734  
 Electrolytic oxidation, of cymene, 263  
 —, of 4-hydroxy-3-methoxy propenol, 272  
 —, of isoeugenol-vanillin solution, 262  
 —, of naphthalenes, 268  
 —, of phenol, 271  
 —, of *m*-xylene, 268  
 Electrolitic tanks, use of cashew shell oil in, 1232  
 Electromagnet cores, from urea resins and iron powder, 623  
 Electromagnetic field, effect on acetylene, 144  
 —, effect on isoprene, 176  
 —, effect on styrene polymerization, 241  
 Electrometric titration, acid numbers, 1260  
 Electronegative substituents, effect on polymerization velocity of olefins, 164  
 Electro-osmosis, removal of catalyst by, 593  
 Electroplating, of molded articles, 484  
 Electropolyolysis, of alcohol, 162  
 —, of acetylene, 162  
 —, of methane, 162  
 —, of petroleum hydrocarbons, 162  
 Element-convertible alkylid resins, properties of, 863, 874, 876, 918, 919, 920, 921, 923, 925, 931, 933  
 Element-convertible resins, classification of, 60  
 —, definition of, 14  
 Elemi, compatibility with chlororubber, 1119  
 —, in urea resin lacquers, 632  
 $\alpha$ -Eleostic acid, nitration, resins from, 731  
 Eleostearic acid, geometrical isomeride in oiticica oil, 861  
 —, properties of, 858  
 —, transformation of, to cyclomonooleostearic acid, 860  
 —, use in alkylid resins, 919, 922, 923, 924, 949  
 Eleostearic acid-maleic anhydride, film-contact angles of, 859  
 $\alpha$ -Eleostearic acid, isolation of, 923  
 —, spectroscopic examination of, 923  
 $\alpha$ -Eleostearic acid-maleic anhydride, structure of, 853  
 $\beta$ -Eleostearic acid, heat-treatment of, 932  
 —, preparation of, 923  
 —, spectroscopic examination of, 923  
 —, use in alkylid resins, 923, 931  
 $\beta$ -Eleostearic acid-maleic anhydride, structure of, 853  
 $\alpha$ -Eleostearic glyceride, from  $\beta$ -eleostearic glyceride, 1216  
 $\beta$ -Eleostearic glyceride, from  $\alpha$ -eleostearic glyceride, 1216  
 $\alpha$ -Eleostearin-maleic anhydride, properties of, 859  
 $\beta$ -Eleostearin, preparation of, 932  
 —, with amberol resin, 494  
 $\beta$ -Eleostearin-maleic anhydride, properties of, 859  
 Ellisols, solubility in aqueous ammonia, 956  
 —, use in impregnation of cloth, 956  
 —, use in impregnation of paper, 956  
 Embrittlement, of varnishes, arc-lamp irradiation tests for, 1368  
 Emery, abrasion resistance tests for varnish with, 1366  
 —, alkylid resin as bonding agent for, 986  
 —, filler, for phenol-formaldehyde resins, 349, 460  
 Emulsifying agent, ammonium oleate, 245  
 —, ammonium sulphuricinate, 1250  
 —, diethylaminoethyloleamide hydrochloride, 245, 246  
 —, saponin, 245  
 Emulsifying agents, albuminous substances, 245  
 —, aldol-urea resins, 672, 684  
 —, chlorinated acids, 1220  
 —, 1-chloronaphthalene-formaldehyde resins, 266  
 —, esters of abietic acid, 829  
 —, for 1,3-dienes, 179, 180  
 —, from naphthenates, 207  
 —, from olive oil and glycol, 994  
 —, from petroleum, 207  
 —, in isoprene polymerization, 178  
 —, modified polyvinyl acetals, 1064  
 —, natural resin-modified phenol-aldehyde resins, 684  
 —, natural resin-modified urea-aldehyde resins, 684  
 —, polyacrylates, 1072, 1075  
 —, polyvinyl acetals, 1061  
 —, sulphonated mineral oils-alcohols condensation products, 268  
 —, sulphonates, 245, 246  
 Emulsions, catalytic polymerization of acrylate esters in, 1076  
 —, incorporation of filler in phenol-aldehyde molding powder with, 457  
 —, of alkylid resins, preparation, 945, 946  
 —, use in treating paper, 945  
 —, of cellulose esters and urea resins, coatings from, 638  
 —, of chlororubber, 1123  
 —, of cumarone resin, 133, 138, 139  
 —, of 1,3-dienes, use of colloids in forming, 179, 180  
 —, of drying alkylid resins, preparation, 946  
 —, of ethyl acrylate and styrene, 246  
 —, of oil-synthetic resin in water, 404  
 —, of petroleum, precipitated by syntans, 420  
 —, of petroleum asphalt reaction products, 274  
 —, of phenol-aldehyde resin, 325, 326, 441, 457  
 —, of phenolic resins in toluene, 457  
 —, of polystyrene, artificial latex, 234  
 —, of polyvinyl acetate, 1027  
 —, of resins, uses, 457, 638, 945, 1334  
 —, of vinyl ethers and acrylic acid derivatives, polymerization, 1076  
 —, polymerization of, 175, 178, 245, 246, 1076  
 —, resolvents, 1158  
 —, styrene, co-polymerization with, 245, 246  
 —, use of, in polymerization of 1,3-dienes, 175, 178, 179, 180, 181  
 —, in co-polymerization of diolefins with monolefins, 193  
 —, in decorating moldings, 1338  
 —, in preparation of molding compositions, 441  
 Emulsoids, viscosity of, 72  
 Enameled vessels, use of phenol-aldehyde resins, 319  
 Enamel-like finishes, from phenol-resin and sodium silicate, 449  
 Enamels, alkylid resins in, 956, 963, 967, 973, 978  
 —, copal esters varnishes and basic pigments in, 319  
 —, cresylic acid-formaldehyde resin in, 368  
 —, cumarone resin in, 129, 132  
 —, effect of benzoic acid on gloss of, 976  
 —, effect of  $\alpha$ -crotonic acid on gloss of, 976  
 —, effect of salicylic acid on gloss of, 976  
 —, ester gum, defects in tropical climates, 318  
 —, ester gum varnish in, 318  
 —, furfural-aniline resin in, 533, 535  
 —, gloss oil in, 773  
 —, gloss-white, formula of, 967  
 —, phenol-carbohydrate resins in, 760

- Enamels, polymers of vinyl ethinyl carbinols in, 151  
 —, polystyrene in, 246  
 —, polyvinyl chloride in, 1040  
 —, synthetic resin, comparison with oil enamels, 974  
 —, synthetic resin, for vitreous enameled ware, 977  
 —, Teglaes in, 912, 956  
 —, tests of yellowing, 819  
 —, vinyl ester-aldehyde resins in, 1065  
 End groups, in polymers, molecular weight determination through, 72  
 —, in polystyrene chain, 223, 234  
 9,10-Endoanthracene- $\alpha$ ,  $\beta$ -succinic anhydride, dissociation of, 840  
 —, formation of, 839  
 2,6-Endocarboxy-4-methylcarboxylate- $\Delta$ 4-tetrahydrophthalic anhydride, synthesis of, 847  
 3,6-Endodimethinehexahydro-tetracarboxylic anhydride, formation of, 837  
 2,5-Endoethylene-cyclohexanone, formation of, 838  
 —, reduction of, 838  
 3,6-Endoethylene- $\Delta$ 4-phthalic anhydride, formation of, 837  
 2,5-Endoethylene- $\Delta$ 3-tetrahydro benzaldehyde, formation of, 838  
 2,5-Endo-isocamylene-1,2,5,6-tetrahydro-1-benzaldehyde, formation of, 843  
 2,5-Endomethylene- $\Delta$ 3-cyclohexenylidene succinic anhydride, 835, 836  
 2,5-Endomethylene-hexahydrobenzaldehyde, preparation of, 834, 835  
 1,4-Endomethylene- $\Delta$ 6-octahydro-2,3-naphthalene-2,3-dicarboxylic anhydride, preparation of, 836  
 3,6-Endomethylene- $\Delta$ 4-phthalic anhydride, use of, in resins, 836  
 2,5-Endomethylene- $\Delta$ 3-tetrahydrobenzaldehyde, formation of, 834, 835  
 3,6-Endomethylene- $\Delta$ 4-tetrahydro-1-methyl-2-cyanobenzene, formation of, 850  
 Endomethylenetetrahydrophthalic acid, 834  
 3,6-Endomethylene- $\Delta$ 4-tetrahydrophthalic anhydride, preparation of, 835  
 3,6-Endomethylene- $\Delta$ 4-tetrahydrophthalic anhydride and butadiene, reaction between, 836  
 3,6-Endomethylene-3,4,5,6-tetraphenyl- $\Delta$ 4-dihydrophthalic acid, formation of, 842  
 —, reaction of, 842  
 Endo-9,10-0-phenylene-9,10-dihydro-1,4-anthraquinone, formation of, 840  
 3,6-Endo-succinic anhydride-4-methyl-carboxylate- $\Delta$ 4-tetrahydrophthalic anhydride, formation of, 847  
 3,6-Endoxo-3,6-dimethyl- $\Delta$ 4-tetrahydrophthalic anhydride, preparation of, 847  
 3,6-Endoxo-hexahydrophthalic anhydride, preparation of, 846  
 3,6-Endoxo-3-methyl- $\Delta$ 4-tetrahydrophthalic anhydride, preparation of, 847  
 3,6-Endoxo-4-methyl- $\Delta$ 4-tetrahydrophthalic anhydride, preparation of, 847  
 3,6-Endoxo- $\Delta$ 4-tetrahydrophthalic anhydride, preparation of, 846  
 —, reduction of, 846  
 Endurance test, dielectric, in laminated products, 1345  
 End-valences, in mechanism for acrylic acid polymerization, 1071  
 Energy of activation, in diolefin polymerization, 51  
 English ester gum, glycerol triacetate crystals from, 806  
 Enneahaptitol, rosin esters of, 796  
 Enol-norcamphor aldehyde acetate, formation of, 854, 855  
 Enzymatic hydrolysis of fatty oils, 928, 930  
 Enzyme, aldehyde, in, 494  
 —, action on cellulose, 750  
 Enzyme, proteolytic, use as protective colloids, 181  
 Epichlorohydrin, catalyst, furfural-phenol condensation, 837  
 —, reaction with phenols, 899  
 —, reaction with quinoline, 739  
 Epichlorohydrin, solvent, for amine-aldehyde resins, 693  
 —, solvent, for urea resin, 631  
 —, stabilizer, for chlorinated rubber, 1111  
 —, stabilizer, for vinyl resins, 1050  
 Epiethylin, solvent, for chlororubber, 1118  
 Epiphenylin, solvent, for chlororubber, 1118  
 Erythrene polymerization, x-ray studies of, 50  
 Erythritol, rosin esters with, 796  
 Esparto grass, waste liquor from, 753  
 Ester gum, adhesives, 821, 824, 828, 1004  
 —, alkali resistance of, 399  
 —, aqueous dispersion of, 824  
 —, catalyst for formation of, 802  
 —, comparison with, hmed rosin, 816  
 —, oil-soluble phenol resin, 409  
 —, Teglaes, 956  
 —, compatibility with chlororubber, 1119  
 —, cumarone resin, 128  
 —, nitrocellulose, 1149  
 —, polystyrene, 248  
 —, tung oil, 26  
 —, dispersions in reclaimed rubber, preparation of, 827  
 —, effect on durability of lacquer films, 826  
 —, from crude turpentine, 795  
 —, in anti-fouling paints, 820  
 —, in aqueous coating compositions, 822, 824  
 —, in bonding compositions, 824, 824, 828, 1004  
 —, in camphor-nitrocellulose compositions, 829  
 —, in chewing gum, 828  
 —, in chloronaphthalene compositions, 1153  
 —, in coating for photographic film, 827  
 —, in core oil, 821  
 —, in electrical insulating varnishes, 819  
 —, in electrical insulations, 820, 826  
 —, in enamels, 818, 819  
 —, in floor coverings, 821, 824  
 —, influence on rate of polymerization of drying oils, 818, 1216  
 —, in lacquers, 424, 632, 818, 822, 824, 825, 826, 827  
 —, comparison with ethyl acetate, 823  
 —, in laminated glass manufacture, 827, 863  
 —, in metal polish, 837  
 —, in mica compositions, 826  
 —, in oilcloth, 820  
 —, in paper coatings, 828  
 —, in plastic compositions, 829  
 —, in printing ink, 826, 827  
 —, in rust-inhibitive primers, 818  
 —, in safety glass manufacture, 827, 863  
 —, in varnishes, 816, 817, 818, 819, 820, 821  
 —, preparation of, 792, 794, 795, 796, 806  
 —, reaction with ethylene oxide, 993  
 —, solvents for, 823  
 —, specifications for use in varnishes, 792, 816  
 —, storage of, 806, 807  
 —, turpentine and castor oil, coating for stencil sheets, 828  
 —, urea resin lacquers with, 632  
 —, with Albertol in varnishes, 820  
 —, with Alkydal resins, 956  
 —, with basic pigments, 818  
 —, with butyl cellulose in lacquers, 824  
 —, with chicle, 828  
 —, with cumarone resin in lacquers, 823  
 —, with ethyl cellulose in lacquers, 824, 825  
 —, with kieselguhr in plastic compositions, 829  
 —, with linseed oil in varnishes, 816  
 —, with methyl cellulose in lacquers, 824  
 —, with naphthol resins, 799  
 —, with nitrocellulose in waterproof sheets, 824  
 —, with oil-treated Rosyls, 773  
 —, with oiticica oil in varnishes, 817  
 —, with paraffin wax and rubber in chewing gum, 828  
 —, with petrolatum wax in waterproofing compositions, 828  
 —, with phenol-aldehyde resins, 799, 820, 821  
 —, with polymerized tung oil, 1218  
 —, with rosin in waterproofing coatings, 827  
 —, with rubber, 837  
 —, x-ray studies of, 88  
 Ester gum and Aroclors, resinous compositions from, 829

- Ester gum and glycerol ester of 9,11-octadecadiene-1-carboxylic acid, in printing ink, 827
- Ester gum-Aroclor resin in nitrocellulose lacquers, 821
- , in oil varnishes, 821
- Ester gum enamels, Albertol primers in, 818
- tests on yellowing, 819
- Ester gum lacquers, effect of dammar in, 823
- , properties of films, 826, 827
- Ester gum modified phenolic resins, x-ray studies of, 87
- Ester gum solution, coating for paraffin paper, 827
- Ester gum-tung-oil-nitrocellulose lacquer, preparation, 825
- Ester gum varnishes, antioxidants in, effect of, 821
- , chloronaphthalenes in, 821
  - , comparison with copal ester varnishes, 819
  - , effect of ozone on, 806
  - , naphthols in, 817
  - , naphthylamines in, 817
  - , paulownia oil in, 817
  - , preparation of, 816, 817
  - , sulphur in, effect of, 821
  - , uses of, special, 819, 820, 821
  - , water resistance of, 818, 828
  - , with mercury salts in anti-fouling points, 820
  - , with metallic powders in coatings, 820
- Esterification, of alkyd resins, effect on electrical resistance, 867, 868
- , of aralkyl halide resins, 1132
  - , of copals, 807, 808, 809, 810, 811
  - , of cork meal, 760
  - , of dammar, 813, 814
  - , of phenol-aldehyde resins, 336, 399, 400
  - , of polyhydric alcohols and polybasic acids, 862-875
  - , of resin acids, 336, 400
  - , of resins, apparatus, 794, 811, 813
  - , of rosin, 26, 792, 793, 794, 795, 796, 799, 800, 801, 805, 806, 810, 811
  - , of shellac, 813
  - , of tall oil, 755
  - , use of inert atmosphere, 813
- Esterified wax, conversion to amides, 815
- Esters, abietic acid, 792, 793, 794, 795, 796, 797, 798
- , acrylic acid, 1069
  - , acrylic acid, polymerization, 1072, 1073
  - , aliphatic, specific viscosity of, 73
  - , benzylamylonic, 762
  - , carbon suboxide from, 1013
  - , condensation with acetylene, 161
  - , condensation with thionyl chloride, 1188
  - , cyclohexanol, fluxing agents, 837
  - , dircinoleic acid, preparation, 1224
  - , esterification of copals with, 809, 810
  - , esterification of rosin with, 800, 801
  - , fatty acid, from tall oil, 756
  - , fatty-acid, reaction with polyhydric alcohols and phenol-aldehyde resins, 428
  - , from tall oil, sulphonation, 756
  - , keto-aromatic acids, plasticizers for polystyrene, 247
  - , modifiers, for alkylated phenol compounds, 411
  - , phosphoric, by fatty acid esters reaction with phosphoric acid, 1233
  - , pimelic acid, with methyl alcohol, 814
  - , polybasic acids with polyhydric alcohols, plasticizers, 613, 823
  - , retarding effect, condensations, 593
  - , rosin, 793, 793, 794, 795, 796, 797, 798
  - , rosin, crystalline, 805, 806
  - , separation of resins from sludge by, 220
  - , solvents, 406, 648, 974
  - , starch, resinous, 762
  - , styrene-maleic anhydride, 244, 245
  - , unsaturated acids, preparation, 1076
  - , use in crimping fibers of diene polymers, 200
- Ester value, 1261
- Ester wax, molding lubricant, polyvinyl acetals, 1063
- Estolides, decomposition to dihydroxystearic acid, 1223
- , from castor oil, formation, 1221, 1224
  - , from dihydroxystearic acid, 1223
  - , —, reaction with glycerol, 1223
- Estolides, from saturated hydroxy acids with mono- and polyhydric alcohols, 1222
- , use in textiles, 1223
- Estolidic acids, chlorides of, treatment of cellulose with, 1222
- E structure in glyceride oils, 860
- Ethane, from lactic acid, 1003
- , halogenated derivatives of, 1154
- 1,2-Ethanedithiol, reaction with dichloroacetic acid, 1170
- , reaction with olefin dihalides, 1170
- "Ethanite," olefin-polysulphide product, 1174
- Ethanol, reaction with acetaldehyde, 495
- Ethanol-acetaldehyde condensation, catalysts for, 495
- Ethanolamines, condensation with phthalic anhydride, 904
- , formation of, 992
  - , in alkyd resin emulsification, 946
- Ethenoid linkage, in polyvinyl ethers, 1011
- Ether, extraction of phenol-aldehyde resins with, 422
- , precipitant, for asphaltenes, 202
  - , —, for paraffin, 202
  - , —, phenol-aldehyde resins, 362
  - , solvent, for aldol, 497
  - , —, for isosuccinic acid-resorcinol resin, 1255
  - , —, for petroleum resins, 202, 229
  - , —, for phenol-aldehyde resins, 278, 283, 284, 367
  - , —, for polymerized olefins, 162, 166, 182, 238
  - , —, for rubber derivatives, 1105, 1114
  - , —, for urea-furfural resin, 670
  - , —, in dehydration of p-hydroxybenzoic acid, 378
  - , —, in lacquers, 374
  - , —, in purification of resins, 336
- Ether acids, resins from, 894, 902
- , condensation with pentaerythritol, 902
- Ether alcohols, modifiers, for phenol-aldehyde resins, 429
- "Ether-linkage formation" of phenol-formaldehyde resin, 297
- Ethers, aromatic, pyrrilium (oxonium) compounds from, 560
- , —, reaction with acetic anhydride and sulphuric acid, 560
  - , —, sulphonamides of, use, 714
  - , cyclic, reaction with hydroxyaromatic alcohols, 431
  - , in chlororubber paints, 1118
  - , in polymerization of 1,3-dienes, 182, 183
  - , mono-allyl, 763
  - , of polyhydric alcohols, 333
  - , retarding effect, condensations, 593
  - , solvents, for vulcanization accelerators, 196
- $\beta$ -Ethoxy-acrolein-acetal, condensation with dimethylaniline, 690
- 6-Ethoxy-8-aminoquinoline, resinification, 739
- o-Ethoxybenzoic acid, condensation, with formaldehyde, 374
- 2-Ethoxy-naphthalene-3-carboxylic acid, condensation with paraformaldehyde, 374
- $\beta,\beta$ -Ethoxyphenylethyl bromide, styrene from, 255
- n-Ethoxypropylbenzene, polymerisation of, 353
- $\alpha$ -Ethoxy-styrene, preparation of, 1010
- Ethyl abietate, condensing agents for, 798
- , gutta-percha and rubber in insulating material, 823
  - , hydrogenation of, 807
  - , in coating compositions, 821, 823, 824
  - , in floor coverings, 824
  - , in lacquers, 823
  - , in smokeless powder, 824
  - , in transfer composition, 829
  - , plasticizer, 823, 829
  - , preparation, 798, 799
  - , solvent for ester gum, 823
  - , —, natural resins, 823
  - , uses of, 821, 823, 824, 829
- Ethylacetanilide, plasticizer for polystyrene, 237, 245
- , —, polyvinyl resins, 1028, 1050
- Ethyl acetate, crystallized methyl ester of shellac with, 813

- Ethyl acetate, glyceryl triacetate crystals with, 805, 806  
 —, modifier, for dihydroxybenzophenone-aldehyde resins, 374  
 —, precipitant, for petroleum resins, 202  
 —, reaction with indolylmagnesium iodide, 743  
 —, solvent for alkyd resins, 956, 967, 968  
 —, — cellulose esters, 402, 412, 960  
 —, — ester gum, 822  
 —, — hydrogenation of esters, 807  
 —, — lacquer, 374, 402, 412  
 —, — phenol-aldehyde resins, 402, 412, 433, 446  
 —, — polystyrene, 236  
 —, — polyvinyl acetate, 1024, 1025  
 —, — rubber compounds, 1110, 1112, 1114  
 —, — urea-formaldehyde condensation, 611  
 —, solvent in polymerization, 172, 993  
 Ethyl acetoacetate, condensation with aldehydes, 546, 576  
 —, — urea and benzaldehyde, 576  
 —, — urea and m-nitro-benzaldehyde, 576  
 —, reaction with tellurium tetrachloride, 1241  
 Ethyl acetoxyacetate, condensation of, 571  
 Ethyl acrylate, adhesive for glass, 1077  
 —, co-polymerized with vinyl acetate, 1075  
 —, from ethyl  $\alpha,\beta$ -dibromopropionate and zinc, 1074  
 —, polymerization, 1073, 1075  
 Ethyl acrylate polymers, properties of, 1073, 1075  
 Ethyl acrylate-styrene emulsions, artificial silk from, 246  
 Ethyl alcohol, acetaldehyde from, 497  
 —, acetic acid from, 496  
 —, diethyl acetal from, 495  
 —, oxidation of, 496  
 —, reaction with acetaldehyde, 495  
 —, — castor oil fatty acids, 1224  
 —, — rosin, 799  
 —, — urea, 663, 664  
 —, solvent, chloroprene polymerization, 157  
 —, —, hydrogenation of esters, 807  
 —, —, phenol-aldehyde resins, 367, 369  
 —, —, preparation of polyvinyl ester-acetals, 1066, 1067  
 —, —, urea-formaldehyde condensation, 612  
 Ethyl allophanate, from biuret, 571  
 Ethylamine, catalyst, cresol condensation, 347  
 —, —, phenol-aldehyde condensation, 162, 347  
 —, —, polymerization of phenylacetylene, 162  
 —, condensation with aldehydes, 706, 710  
 Ethyl aniline, reaction with boron triphenyl, 1241  
 Ethylazocarboxylate and dimethyl isoprene, reaction, 831  
 Ethyl-p-oxocinnamate, hydrolysis, 734  
 Ethylbenzene, chlorination, catalyst, 253  
 —, condensation with ethylene dihalides, 266  
 —, — isoprene, 193  
 —, — maleic anhydride, 839  
 —, — dehydrogenation of, 235  
 —, from benzene, 252  
 —, from cumarone, resin, 95  
 —, from styrene, 242  
 —, pyrolysis of, 242, 252, 253, 254  
 —, styrene from, 235, 242, 252, 253, 254  
 —, styryl dibromide from, 253  
 Ethyl benzoate, plasticizer, alkyd resins, 882, 890  
 —, —, polyvinyl chloride, 1038  
 —, solvent, chloroprene polymerization, 157  
 Ethyl benzoacetate, effect on polymerization of 1,3-dienes, 184  
 Ethyl benzoylebenzoate, plasticizer, 942  
 Ethyl benzenesulphonate, preparation of, 576  
 Ethyl benzylideneacyanoacetate, reduction of, 638  
 Ethylbiphenyl, styrene homologues from, 254  
 Ethyl-bis-(4-aminophenyl)-methane hydrochloride, nitration, tars from, 725  
 Ethyl bromide, reaction with potassium pentasulphide, 1170  
 —, reaction with sodium tetrasulphide, 1170  
 Ethylbromoketene, polymerization, 553  
 Ethylbutenetetracarboxylate, hydrolysis, 1241  
 N-Ethylcarbazole, condensation with propylene, 744  
 Ethylcellulose, glycerol linoleate with, 969  
 —, glycerol ricinoleate with, 969  
 —, lacquers from, 824, 825  
 Ethylcellulose, modifier, phenol-aldehyde resins, 423  
 —, transfer compositions, 829  
 —, with ester gum in lacquers, 824, 825  
 —, with oil modified-alkyd resins in varnishes, 973  
 Ethyl cellulose ethers, phenol resin varnishes with, 446  
 Ethyl chloride, chlorination of benzene, 252  
 —, reaction with hexamethylenetetramine, 707  
 —, — pentaerythritol, 901  
 —, — polyvinyl alcohol, 1059  
 Ethyl chloroformate, reaction with diversane, 745  
 Ethyl chloro-oxylate, reaction with magnesiulindole, 743  
 Ethyl cinnamate, in polymerization of 1,3-dienes, 181  
 —, polymerization of, 1082  
 —, —, x-ray studies, 50  
 Ethyl cyanoacetate, reaction with sodium ethoxide and phenylmethylacetone, 723  
 Ethyl  $\alpha$ -cyano- $\beta$ -amino- $\alpha$ -phenyl-valerate, preparation, 733  
 —, reaction with sulphuric acid, 733  
 Ethyl N- $\alpha$ -cyanopiperonylamino acetate, action of alcoholic potash, 733  
 Ethyl cyclohexanone-2-carboxylate, resin from resorcinol, 391  
 Ethyl 2,4-diamino-1-methylnaphthalene-3-carboxylate, resinification, 723  
 Ethyl dibromobutanetetetracarboxylate, reaction with phenol, 1141  
 Ethyl  $\alpha,\beta$ -dibromopropionate and zinc, ethyl acrylate from, 1074  
 Ethyl dihydroxymethylmalonate, decomposition of, 1074  
 Ethyl 4,6-dimethylpyrrole-3-carboxylate, condensation with aldehydes, 741  
 Ethylene, acetylene from, 165  
 —, action of electric discharge on, 165  
 —, acrylic acid from, 1070  
 —, aluminum chloride in polymerization of, 166  
 —, 1,3-butadiene from, 165  
 —, 1-butene from, 165  
 —, effect of silent electric discharge on, 165  
 —, electropolymerization of, polymerization of products from, 165  
 —, from ethyl alcohol and carbon dioxide, 1070  
 —, from pyrolysis of ketene, 555  
 —, 1-hexene from, 165  
 —, in polishing wax, 993  
 —, polymerization of, 164, 165  
 —, reaction with acetylene, 184  
 —, — cyclohexane, 194  
 —, — naphthalene, 194  
 —, resinous materials from, 165  
 —, styrene from, 253  
 —, vinyl ethers from, 1008  
 Ethylene bromide, polyethylene glycols from, 990  
 —, solvent, for phenylacrylic acid esters, 1083  
 Ethylene bromohydrin, rosin esters with, 797  
 Ethylene carbonate, 855  
 Ethylene chloride, effect on pyrolysis of ethylbenzene, 254  
 —, pyrolysis of, 1035  
 —, reaction with sodium acid sulphide, 1172  
 —, solvent in chloroprene polymerization, 157  
 Ethylene chlorohydrin, ethylene oxide from, 990  
 —, hydrolysis of, 356  
 —, modifier, urea-aldehyde resins, 665, 667  
 —, preparation of Plastopals in, 634, 635  
 —, reaction with aniline and phenol, 1138  
 —, — diphenylpropanetetetracarbinol, 429  
 —, — ethylene oxide, 993  
 —, — rosin esters with, 797  
 Ethylene cyanohydrin, acrylic esters, 1074  
 —, hydrolysis, 1070  
 Ethylene diamine, catalyst, urea-acrolein reaction, 670  
 —, reaction with  $\beta$ -naphthol, 732  
 Ethylenediamine-N,N'-dicarboxylic diamide, reaction with formaldehyde, 665  
 Ethylene dibromide, ethylene oxide from, 990  
 —, reaction with ethylene trithiocarbonate, 1160  
 —, — organic salts of silver, 887, 889

- Ethylene dibromide, reaction with potassium adipate, 892
- Ethylene dibromosuccinate, 889
- Ethylene dichloride, acetylene from, 1035
- , action on peat residues, 749
- , rubber, 1101
- , hydrogen acceptor, 254
- , in polymerization of 1,3-dienes, 180, 183
- , reaction with alcoholic potash, 1035
- , calcium polysulphide, 1173
- , hydrocarbons, 159, 1137
- , inorganic salts of sodium, 1172, 1174, 1179
- , phenols, 429
- , potassium sulphide, 1169
- , sodium ethoxide, 1003, 1035
- , solvent, for chlororubber, 1118
- , for cold-molding composition, 1288
- , for polyvinyl acetate, 1024
- , vinyl chloride from, 1035
- Ethylene fumarate, 889
- Ethylene glycol, condensation with adipic acid dichloride, 892
- , ammonium borate and boric acid, 893
- , benzophenone-2,4'-dicarboxylic acid, 895
- , carbonic acid derivatives, 882
- , chloroformic ester, 870
- , dimethyl oxalate, 885
- , ethyl oxalate, 885
- , glutaric acid, 893
- , oxalic acid derivatives, 862
- , phenols, 393
- , phosgene, 870
- , phthalic anhydride, 897, 902
- , sebacic acid, 892, 999
- , succinic acid, 871, 872, 869, 870, 871, 999
- , thiourea, 659, 664
- , urea, 659
- , condensing agent, pyrrole, 740
- , dioxane from, 1253, 1254
- , ethylene oxalate from, 1001
- , fluxing agent, 337
- , from ethylene oxide, 990
- , hexamer of, 990
- , in acetylene polymerization, 149
- , modifier, urea-aldehyde resin, 678
- , plasticizer, cellulose acetate-urea resin composition, 623
- , reaction with vegetable oils, 991
- , resins from, 1253, 1254
- , rosin esters of, 796
- , solvent, for chlororubber, 1118
- , for cold-molding composition, 1288
- , for digyanodiamide-formaldehyde resin, 680
- , for polyvinyl alcohol, 1054, 1056
- , for shellac, 1006
- , uses of, 904, 981, 984, 989, 1005, 1255
- Ethylene glycol adipate ricinellidin modified resin, 908
- Ethylene glycol and ethyl oxalate, polymerization products from, 871
- Ethylene glycol ester of drying oil, nature of drying, 920
- Ethylene glycol monoacetate, solvent, for intaglio printing colors, 962
- Ethylene glycol monoethyl ether, solvent, for alkyl resins, 884
- , for thiourea resin, 654
- Ethylene glycol mononaphthyl ether, reaction with formaldehyde, 876
- Ethylene glycol monophenyl ether, reaction with formaldehyde, 876
- Ethylene glycol monotolyl ether, reaction with formaldehyde, 876
- Ethylene glycol oxalate, monomeric ester from, 863
- Ethylene glycol-phthalic anhydride resin, in lacquers, 966
- Ethylene glycol-phthalic anhydride resin, properties of, 864, 867
- Ethylene glycol succinate, emulsification of, 946
- Ethylene malonate, properties of, 873
- Ethylene mercaptan, in olefin polysulphides, 1173
- Ethylene oxalate, polymerization of, 1001
- , preparation of, 886, 1001
- Ethylene oxide, catalyst, chloroprene polymerization, 158
- , catalysts in polymerization of, 990, 991
- Ethylene oxide, dioxane from, 993
- , ethylene glycol from, 990
- , polyethylene glycol from, 990
- , polymerisation, 990, 991, 992, 993
- , polymers with ethylene chlorohydrin, 992
- , polysaccharides from, 992
- , preparation of, 990
- , reaction with albumin, 993
- , cellulose, 900
- , colophony, 797, 993
- , cresol, 430
- , ester gum, 993
- , glycerol, 899
- ,  $\alpha$ -methyladipic acid, 892
- , pentaerythritol, 899
- , phenol, 255
- , phthalic anhydride, 898
- , phthalic glyceride resins, 993
- , polyvinyl alcohol, 1060
- , shellac, 993
- , succinic acid, 893
- , triethylene glycol, 899
- , water, 990
- , solid, 990
- , solvent, for polyvinyl chloride, 1040
- , therapeutic agents from, 993
- , waxy material from, 993
- Ethylene oxide-abietic acid ester, uses of, 823
- Ethylene-oxide polymer, softening agent, phenaldehyde resins, 441
- Ethylene polysulphide, molding, 1174
- , vulcanization, 1171, 1172
- , with rubber, 1172
- , with sulphur, 1174
- , x-ray pattern of, 83, 89
- Ethylene sebacate, fibers from, 90
- , properties of, 872
- Ethylene succinate, preparation, 887
- Ethylene-succinate-glycerol-phthalate resin, 813
- Ethylene sulphide, polymerization, 1169
- , action of phenol on, 116<sup>c</sup>
- , preparation of, 1169
- , properties of, 1169
- Ethylene trithiocarbonate, reaction with ethyl dibromide, 1169
- Ethyl ester, of acrylic acid, preparation of, 1
- , of methylacrylic acid, resins from, 1081
- , of phenylacrylic acid, polymerization, 1083
- Ethyl ether, action on chlororubber, 1118
- , in polymerization of 1,3-dienes, 182
- Ethyl formate, solvent, for polyvinyl acetate, 1
- Ethylglycolyl chloride, reaction with magnesium pyrrrole, 742
- Ethylhexahydrophenyldithiocarbamic acid, hexal droaniline salt of, 1197
- Ethyl hydracrylate, acrylic esters from, 1074
- , dehydration catalysts for, 1074
- 2-Ethyl-1-hydrindone, condensation with phenylhydrazine, 735
- Ethyl hydrogen 3,6-endoxhexahydrophthal preparation of, 846
- Ethyl p-hydroxybenzoate, condensation with methylal, 374, 375
- Ethyl  $\beta$ -hydroxyethyl oxalate, from ethylene glycol and ethyl oxalate, 885
- Ethylideneacetone, polymerization of, 562
- Ethylidene aniline, cuprous chloride catalyst preparation of, 149
- , from acetylene and aniline, 148, 149
- , polymers, 148, 149
- Ethylidene diacetate, from acetylene and acetic acid, 1017, 1018, 1019
- , reaction with inorganic acids, 1019
- , polyvinyl esters, 1066
- , vinyl acetate from, 1019
- Ethylidene-dianiline, from aniline and acetaldehyde, 689
- Ethylidene dichloride, pyrolysis, 1035
- , vinyl chloride from, 1035
- Ethylidene dihalides, vinyl ethers from, 1003
- Ethylidenedi- $\alpha$ -naphthol, from  $\alpha$ -naphthol acetaldehyde reaction, 283
- Ethylidenediphenol, formation of, 283
- Ethylidene glycol, formation of, 1009
- Ethylidene peroxide polymers of, 493

- Ethyl indeneoxalate, from indene, 98  
 —, structure of, 98  
 Ethyl  $\beta$ -indoleglyoxylate, reaction with benzene diazonium chloride, 743  
 Ethyl iodide, saliretin preparation with, 282  
 Ethyl isocarbamide, condensation with acetylacetone, 871  
 S-Ethyl isothiourae, from ethylmercaptan and cyanamide, 653  
 Ethyl itaconate, polymers of, 1085, 1086  
 Ethyl lactate, solvent, for alkyd resins, 880, 925, 960, 964, 966, 967  
 —, —, for cellulose esters, 960, 967  
 —, —, for thiourea resin, 654  
 —, —, for urea-phenol-aldehyde resin, 676  
 Ethylmagnesium iodide, reaction with dipropargyl methylene ether, 1254  
 Ethyl malonate, reaction with aniline, 733  
 —, reaction with selenium tetrachloride, 1241  
 Ethyl mercaptan, catalyst, cyclopentadiene polymerization, 186  
 —, reaction with cyanamide, 653  
 $\alpha$ -Ethyl- $\beta$ -methylacrolein, reaction with aniline, 706  
 Ethylnaphthalene, pyrolysis of, 254  
 —, vinylnaphthalene from, 254  
 Ethyl nitrite, reaction with phenylcyclohexanone, 725  
 10-Ethyl-9-nitroso-9,10-dihydrophenarsazine, resins from, 727  
 Ethyl oleate, chlorinated, in lubricating oil, 1158  
 $\alpha$ -Ethylnaphthalene,  $\alpha$ -vinylnaphthalene from, 254  
 Ethyltoluenesulphonamide, plasticizer, 717  
 Ethyl orthosilicate, preparation of, 1236  
 —, reaction with acetic acid, 1236  
 —, — ethyl ricinoleate, 1237  
 —, — water vapor, 1286  
 Ethyl oxalate, reaction with ethylene glycol, 871, 885  
 —, — indene, 98  
 o-Ethylphenol, from cumarone dibromide, 94  
 —, from cumarone resin, 95  
 Ethyl phthalate, plasticizer, 1246  
 Ethyl polyacrylate, adhesive, 1077  
 —, gas-imperious sheets from, 1078  
 —, hydrolysis of, 1069  
 $\alpha$ -Ethyl- $\beta$ -propylacrolein, reaction with aniline, 505  
 Ethyl ricinoleate, reaction with ethyl orthosilicate, 1237  
 Ethyl salicylate, reaction with formaldehyde, 374  
 Ethyl selenide, effect on chloroprene polymerization, 156  
 Ethyl sorbate, in polymerization of 1,3-dienes, 181  
 p-Ethylstyrene, polymerization of, 259  
 Ethyl succinate, reaction with benzaldehyde, 1253  
 Ethylsulphuric acid, catalyst, phenol-formaldehyde polymerization, 320  
 Ethyl tartrate, solvent for cellulose esters, 39  
 Ethyl titanate, films from, 1239  
 —, preparation of, 1239  
 Ethyltoluene, styrene homologues from, 254  
 Ethyl toluenesulphonamide, plasticizer for molding compositions, 720  
 Ethyltoluenesulphonamide resin, adhesive for shatterproof glass, 719  
 Ethylurea-formaldehyde resin, opacity to ultraviolet rays, 603  
 Ethylvinylcarbinol, hydrogen succinate, alkaloid salts, 745  
 Ethyl vinyl ether, polymerization of, 1010  
 —, preparation of, 1008  
 Ethyl vinyl ether of ethylene glycol, preparation of, 1007  
 Eu colloidal polystyrene, from styrene, 235  
 Eu colloids, formation of, 57  
 —, properties of, 57  
 Eugenol, bromination of, 1154  
 —, condensation with formaldehyde, 375  
 —, oxidation inhibitor, 408, 976  
 —, polymerization of, 260, 261, 262  
 Eugenol-formaldehyde resin, use in dentistry, 375  
 Eugenyl vinyl ether, preparation of, 1008  
 Euphorbium resin, in preparation of non-splintering glass, 963  
 —, in urea-phenol-aldehyde adhesive, 676  
 Eutectic plastic masses, nitro-compounds, 727  
 Evaporation rate, electrical measurements, 601  
 Eyes, artificial, from vinylite resins, 1045  
 Explosive-proof lubricant, 996  
 Explosives, from cuprene, 146, 147  
 —, from acetylene derivatives, 148, 152, 160, 161  
 Exposure, effect on electrical properties of laminated materials, 1350  
 Exposure tests, alkyd resin coatings, 957, 958, 959, 961  
 —, Aroclor lacquers, 1148  
 —, polystyrene coatings, 246  
 —, varnishes, 818, 1368, 1369, 1371, 1376  
 Extending agents, for chlororubber, 1126  
 —, for phenol-aldehyde resins, 286  
 Extensometer, in determination of elasticity, 1341  
 Extraction, of flowers, 1250  
 —, of furfural, 517  
 —, of molasses, resin from, 762  
 —, of phenol-aldehyde resin, 361  
 —, of phenols, from coal tar, 362  
 —, of pine wood, 764  
 —, of polyvinyl alcohol, 1055  
 —, of resins, from acid tar, 121  
 Extrusion compositions, alkyd resins in, 981  
 Extrusion molding, definition of, 1322, 1323  
 —, polyesters to form filaments, 998, 999  
 —, polystyrene resin, 249, 250  
 —, products of, 998, 999, 1294, 1322, 1323
- ### F
- Fabric fillers, in molding compositions, 1319, 1330, 1330  
 Fabric linings, in polymerization apparatus, 179  
 Fabrics, acid-resistant, 1248  
 —, adhesive to unite rubber to, 1100  
 —, coatings for, 199, 378, 978, 1209  
 —, fireproof, 1127  
 —, gas-imperious, 1027  
 —, impregnation of, with chlororubber, 1127, 1128  
 —, —, with cumarone resin, 135  
 —, —, with dimethylacetone, 544  
 —, —, with phenol resins, 452, 470, 471, 486  
 —, —, with polystyrene, 248  
 —, —, with resins, 1167, 1281  
 —, —, with sulphur-olefin resin, 1178, 1177  
 —, —, with urea resin, 588  
 —, in decorating moldings, 1333  
 —, in dental plates, 465  
 —, in laminated material, 987, 1247, 1274, 1281  
 —, molding fasteners on, 1334  
 —, waterproof, 135, 138, 139, 360, 430, 432, 1127  
 Factice, addition to vinyl resins, 1031  
 —, as rubber substitute, 1211, 1212  
 —, brown, 1211  
 —, from fatty oils and sulphur, 1211  
 —, — and sulphur chloride, 1211-1214  
 —, from mineral oils and sulphur chloride, 1212  
 —, from triolein and sulphur, 1211  
 —, modifier, phenol-aldehyde resins, 441, 1212  
 —, plasticizer, for phenol-resin adhesives, 486  
 —, reaction with amines, 1213  
 —, resemblance of phenol-furfural resin to, 522  
 —, use in linoleum, 1212, 1246  
 —, — safety glass, 1213  
 —, white, 1210, 1211  
 Fat oil, preparation of, 780, 781  
 Fats, chlorination of, 1220, 1221  
 —, chloronaphthalene-aldehyde resins as solvents for, 266  
 —, mixtures with phenols, sulphonation of, 431  
 —, plasticizers, for cumarone resin, 120  
 —, —, for synthetic resins, 1246  
 —, —, for urea resins, 623  
 —, reaction with acetylene, 161  
 —, sulphur-containing solvents for, 1210  
 —, use in polishing compositions, 1351  
 —, with polyvinyl alcohol in sisings, 1058  
 Fatty acid esters, halogenated, plasticizers for phenol resins, 423  
 —, in hexachloroethane-tar compositions, 1156  
 —, solvents for xylenol-aldehyde resins, 370

- Fatty acid glycerides, effect on phenol-aldehyde resins, 397
- Fatty acid residues, esterification, 815
- , vulcanization of, 1204
- Fatty acids, alcohols from, 994
- , catalysts, phenol-formaldehyde reaction, 350, 351, 357
- , effect on alkyd resin films, 974
- , from autooxidation of turpentine resins, 1253
- , from wood, 749
- , halogenated, plasticizers for phenol resins, 432, 446
- , halogenation of, 1139, 1158, 1220
- , in tall oil, 755
- , long-chain, addition to vinyl resins, 1031
- , modification with electrolytes, 1227
- , of glycerides, displacement with rosin acids, 803
- , of Japanese sardine oil, polymerization, 1229
- , of linseed oil, reaction with glycerol, 646
- , of oiticica oil, solubility, 1232
- , of waxes, reaction with sulphur monochloride, 815
- , oxidized with alkali metal hydroxides, 1227
- , alkali metal oxides, 1227
- , alkali metal peroxides, 1227
- , plasticizers for nitrocellulose, 970
- , reaction with amino compounds, 1228
- , higher alcohols, 1233
- , phenols, 1233, 1234
- , triethanolamine, 1233
- , shellac substitutes from, 1139
- , unsaturated, solvent for shellac, 1228
- , use in decoration of phenol resins, 484

 Flint, filler, 1275  
 Floor covering, alkyd resins in, 923, 949, 978, 983, 984, 985  
 —, chlorinated biphenyls in, 1150  
 —, chlorinated naphthalenes in, 1150  
 —, cumarone resin in, 127, 130, 137, 138  
 —, ester gum in, 821, 824  
 —, ethyl abietate in, 824  
 —, modified phenol-aldehyde resin in, 416  
 —, polyacrylic acid derivatives in, 1078  
 —, vinyl resins in, 1050  
 Floor tiles, cumarone resin in, 128, 137, 138  
 —, ester gum in, 824  
 Floor wax, alkyd resins in, 924  
 —, alkylene oxide polymers in, 993  
 —, sulphur in, 1164  
 Floral wax, nature of, 1250  
 Florida earth, catalyst, polymerization, 50  
 —, extractant, petroleum resins, 202, 203  
 Floridin, catalyst, polymerization, 166, 226  
 Flotation agent, from pine oil, 1200  
 —, phenol-sulphur resin as, 1186, 1190  
 Flour, potato, infusible products from, 760  
 —, wheat, use in urea-aldehyde resins, 623, 683  
 Flowing characteristics, of alkyd resin varnishes, 978  
 —, of molding preparations, 1329, 1330  
 —, —, tests for, 1358  
 Flow marks, on moldings, 1329, 1330  
 Flow point, of flexible alkyd resins, 873  
 Flow sheet, for manufacture of furfural, 518  
 —, for manufacture of toluenesulphonamide, 713  
 —, for manufacture of urea, 568  
 Fluavil, from gutta-percha, 1091  
 Fluoboric acid, action on rubber, 1102  
 —, reaction with vinyl compounds, 1057  
 Fluoboroacetic acid, catalyst, cumarone polymerization, 117, 119  
 Fluorene, reaction with formaldehyde, 265  
 Fluorescein test, for phthalic anhydride, 957  
 Fluorescence, of resins, 714, 1263  
 Fluorescent paint, composition of, 1091  
 Fluoridenes, dyes for polystyrene, 237

- Fluorides, action on rubber, 1102  
 Fluorination, of hydrocarbons, 1151, 1156  
 Fluorobromomethylene, oxidation, 1042  
   —, polymerisation, 1042  
 Fluosilicates, modifiers for syntans, 421  
 Flux, soldering, metallic soaps in, 791  
 Fluxing agents, for molding compositions, 1277  
   —, for phenol-aldehyde resins, 318, 337  
   —, for urea-aldehyde resins, 593  
 Fly paper, chlororubber in, 1127  
   —, phenol-sulphur resin in, 1186  
 Foaming agents, from polyethylene glycols, 593  
   —, from sulphonated methylenediphenols, 422  
 Foam prevention, in methylolurea, 593  
 Foils, condenser, chloronaphthalene in, 1152  
   —, from polymers of 1,3-dienes, 185  
   —, waterproof, alkyd resins in, 970  
 Folded molecules, description, 70, 71  
 Food-containers, metal, phenol-resin coatings for, 448  
 Foots, from glycerol distillation, 994  
 Formaldehyde, action on hydrolyzed vinyl acetate-maleic anhydride co-polymer, 1066  
   —, — hydrolyzed vinyl ester-aldehyde resin, 1066  
   —, — oil-soluble phenol-aldehyde resins, 368  
   —, — pectous material, 762  
   —, — petroleum resins, 202, 203

 —, in rubber accelerators, 705  
 —, polymerization of, 505  
 Heptamethylene carbonate, dimer of, 870  
 Heptanaphthene, action of aluminum chloride on, 215  
 Heptene oxide, preparation, 1254  
 —, resin from, 1254  
 Heptate, of castor oil fatty acids, preparation, 1224  
 1-Heptyne, polymerization of, 161, 162  
 Hercolyn, plasticizer, chlororubber, 1119  
 Heteropolymerization, 42, 43  
 —, acrylic acid derivatives with maleic anhydride, 1076  
 —, cyclohexanol with styrene, 244  
 —, indene and maleic anhydride, 100  
 —, of olefins, factors affecting, 168  
 —, stilbene with maleic anhydride, 100, 854  
 —, styrene and dimethylmaleate, 246  
 —, styrene with ethylacrylate, 246  
 —, styrene with maleic anhydride, 244, 245  
 Heven, formation of, and formula, 1089  
 Hexabromooctadecaric acid, formation of, 858  
 Hexabromo-3-hexene, from divinylacetylene, 182  
 Hexachlorobiphenyl, as paper impregnant, 1150  
 Hexachloroethane, in fireproof coatings, 1156  
 —, use in heteropolymerization of styrene, 246  
 —, use in polymerization of diolefins, 180  
 Hexadecamethylene dicarboxylic acid, polyester-polyamides from, 1000  
 Hexadecamethylene dicarboxylic acid, reaction with trimethylene glycol, 998  
 Hexadiene, condensation with aromatic hydrocarbons, 194  
 Hexadiene, formation of, 1089  
 1,5-Hexadiene-3-yne, from acetylene, 144  
 1,5-Hexadiyne, polymerization of, 162  
 Hexaglycerol octa-acetate, preparation of, 995  
 Hexahydroaniline salt of ethylhexahydrophenyl-dithiocarbamic acid, preparation of, 1197  
 Hexahydroanthraquinones, formation of, 832  
 Hexahydrodiphenylene oxide, pyrolysis of, 94  
 Hexahydrodiphenylene oxide, reaction with acetyl chloride, 1188  
 Hexahydrophthalide, plasticizer for polystyrene, 247  
 Hexahydrophthalide, properties of, 941  
 Hexahydropropylindene, from polyindene, 105  
 cis-p-Hexahydroterephthalic acid, reaction with acetic anhydride, 999  
 Hexahydroterephthalic anhydride, polymerization of, 999  
 Hexahydroterephthalic polyanhydride, distillation of, 999  
 Hexahydro-1,3,5-triazines, rubber accelerators and anti-agars, 710  
 Hexahydroxycyclohexane, condensation with phthalic anhydride, 904  
 Hexahydroxysebacic acid, use in alkyd resins, 910  
 Hexalin, solvent in cold-molding composition, 1288  
 Hexamethylbenzene, condensation with isoprene, 193, 194  
 Hexamethylbenzene, decomposition of, 266  
 Hexamethylene carbonate, dimer of, 870  
 Hexamethylene carbonate, properties of, 872  
 Hexamethylene glycol oxalate, polymerization of, 871  
 Hexamethylenetetramine, ammonia from, 318, 327, 444  
 —, ammonia addition by, 321  
 —, and ethyl abietate, soldering flux, 829  
 —, catalyst, polymerization of formaldehyde, 512  
 —, —, polymerization of vinyl acetate, 1023  
 —, condensation with diphenylcarbonate, 377  
 —, — rosin, 769  
 —, — starch, 758

- , catalyst, phenol-formaldehyde reaction, 348
- , hardening agent, phenol-aldehyde resins, 431
- Hydrobromic acid, action on cumarone, 94
- , — vinylacetylene, 159
- Hydrobutadiene rubber, preparation of, 1096
- Hydrocarbon oils, media, tung oil polymerization, 1216
- Hydrocarbon polymers, from benzyl chloride, 1120

Hydrocarbon residues, tanning agents from, 750  
 Hydrocarbons, action of canal rays on, 269  
 —, aromatic, cracking of, 284  
 —, reaction with ethylene dichloride, 1187  
 —, reaction with maleic anhydride, 839  
 —, chlorinated, condensation media for urea resins, 617  
 —, in paints, 220  
 —, in purifying cumarone resins, 118  
 —, resins from, 221  
 —, styrene from, 252, 253  
 —, chlorinated in presence of phenol, 221  
 —, coal-tar, solubility of oxidizing alkyds in, 923, 933  
 —, condensation medias, urea resins, 617  
 —, condensation with acetylene, 161  
 —, aldehydes, 265  
 —, benzyl chloride, 1131  
 —, cyclic, from butadiene hydrocarbons, 172  
 —, dehydrogenation of, 216  
 —, effect on phenol-aldehyde condensation, 363  
 —, rubber hydrochloride, 1112  
 —, from polystyrene depolymerisation, 234  
 —, from styrene polymerisation, 234  
 —, halogenated, in artificial shellac, 369  
 —, media, castor oil polymerisation, 1222  
 —, modifiers, urea-aldehyde resins, 684  
 —, nitrated, condensation media for urea resins, 617  
 —, oxidation of, 1233  
 —, oxidised, esterification of, 911  
 —, petroleum, solubility of modified alkyd resins in, 934, 935  
 —, reaction with sulphur, 215, 1183  
 —, sulphur chloride, 215, 216, 1203  
 —, saturated, by polymerization of olefins, 164, 167  
 —, solvents, diolefin-monoolefin co-polymerization, 193  
 —, phenol-oil-aldehyde resins, 406  
 —, resin from cracked gasoline, 192  
 —, vulcanisation accelerators, 196  
 —, xylene-formaldehyde resin, 370  
 —, styrene from, 253, 254  
 —, unsaturated, by action of silent discharge on isobutylene, 165  
 —, from lactic acid, 1003  
 —, reaction with nitrogen peroxide, 727  
 —, use in aldehyde-tar acid condensation, 363  
 Hydrocarbon-soluble Rezyls, 968  
 Hydrocarbon vapors, effect of electrodeless discharge on, 269  
 Hydrocellulose, filler, for molding composition, 463  
 —, effect on, blistering, urea resins, 620  
 Hydrochloric acid, accelerator, solidification of urea resins, 617  
 —, action on alkylfurylcarbinols, 520  
 —, chitin, 1255  
 —, chlororubber paints, 1121  
 —, furfural, 521  
 —, hexamethylenetetramine, 309  
 —, hydrogen-carbon monoxide product, 1255  
 —, indene, 102  
 —, rosin, 766, 769  
 —, activator, for hydrogenation of esters, 807  
 —, catalyst, acetaldehyde-naphthylamine, 708  
 —, aldehyde-acid amide reaction, 639  
 —, aldehyde-alkylcarbazole reaction, 744  
 —, amine-aldehyde reaction, 700, 701, 706, 707  
 —, aniline-formaldehyde reaction, 690, 691, 692  
 —, benzaldehyde-naphthylamine reaction, 710  
 —, benzaldehyde-pyrogallol-aldehyde reaction, 277  
 —, catechol-acetone reaction, 287  
 —, condensation of phenol and vinyl esters, 1081  
 —, cyclohexanone-phenol reaction, 390, 560  
 —, dicyanodiamide-formaldehyde reaction, 680, 681  
 —, esterification of montan wax, 814  
 —, shellac, 813  
 —, formaldehyde and ammonium thiocyanate reaction, 660  
 —, formaldehyde-benzaniline reaction, 690  
 —, formaldehyde-dimethylaniline reaction, 687  
 —, formaldehyde-glycol-monoaryl ether reaction, 576

Hydrochloric acid, catalyst, formaldehyde-pyrrole condensation, 741  
 —, formaldehyde reaction with p-toluene-sulphon-ethylamide, 712  
 —, formaldehyde-salicylic acid reaction, 374  
 —, formaldehyde-p-toluidine reaction, 687  
 —, formalin-cashew-shell oil reaction, 1230  
 —, furfural-acid amide condensation, 535  
 —, furfural-amine condensation, 534  
 —, furfural and cracked distillate condensation, 527  
 —, furfural-phenol condensation, 521, 522, 523, 526, 534  
 —, lignin-furfural condensation, 748  
 —, methylene acetate-phenol reaction, 279  
 —, oxidation of acetaldehyde resin, 492  
 —, paraformaldehyde and 2-ethoxynaphthalene-3-carboxylic acid reaction, 374  
 —, phenol-acetaldehyde reaction, 233, 381, 382  
 —, phenol-acetone reaction, 386, 388, 389, 410  
 —, phenol-aldehyde reaction, 278, 279, 285, 288, 296, 323, 333, 346, 348, 350, 351, 352, 353, 355, 366-369, 378, 392, 397, 398, 422, 426, 429, 430, 439  
 —, phenol-aldehyde-carboxylic acid reaction, 375, 394  
 —, phenol-furfural reaction, 672  
 —, phenol-glycerol reaction, 393  
 —, phenolketo-carboxylic acid reaction, 375  
 —, phenol-lignin condensation, 747  
 —, phenol-methylal reaction, 394  
 —, polymerization of isoprene, 174  
 —, styrene, 241  
 —, vinyl chloride, 1040  
 —, preparation of ethyl abietate, 798  
 —, polyvinyl acetals, 1061  
 —, polyvinyl ester-acetals, 1065, 1066, 1067  
 —, sulphonanilide resins, 715  
 —, reaction of acetaldehyde and hydrogen sulphide, 1180  
 —, reaction of essential oils with phenols, 383  
 —, resinification of acetaldehyde, 493  
 —, corncoobs with phenol, 526  
 —, furyl alcohol, 522  
 —, resorcinol-acetone reaction, 373, 387  
 —, rosin-aldehyde condensation, 776  
 —, saliretin preparation, 281, 282  
 —, thiourea-furfural condensation, 658  
 —, urea-aldehyde reaction, 589, 613, 635, 637, 671  
 —, urea-furfural reaction, 669, 670  
 —, urea-phenol-aldehyde resins, 676, 678  
 —, urethan-aldehyde reaction, 682  
 —, xylene ether-formaldehyde condensation, 371  
 —, hardening agent, phenol-aldehyde resins, 449  
 —, polyvinyl esters, 1029  
 —, urea-aldehyde resins, 598, 662  
 —, in varnishes, prevention of yellowing, 1378  
 —, precipitant, almond-oil resin, 1253  
 —, reaction with acetylene, 149  
 —, calcium carbide, 1036  
 —, dianilinothiourea, 733  
 —, formaldehyde, 342  
 —, monothioarsaldehyde, 1180  
 —, pyrrole, 740  
 —, removal from phenol-sulphur resins, 1186  
 —, use in scrap resin recovery, 629  
 Hydrochlorides, of divinylacetylene, 152  
 Hydrofluoric acid, as polymerisation catalyst, 50  
 —, catalyst, styrene polymerisation, 241  
 —, effect on films of acetylene polymers, 154  
 —, polystyrene, 237  
 —, hardening agent, urea-formaldehyde resins, 598  
 Hydrogen, catalyst, drying oil polymerisation, 1238  
 —, effect on rosin ester formation, 794  
 —, from ethylene, 165  
 —, from hydrolysis of phenol-formaldehyde resin, 307  
 —, from lactic acid, 1003  
 —, from polymerisation of acetylene, 143  
 —, reaction with carbon monoxide, 553  
 —, ngaiol, 560  
 Hydrogenated aromatic hydrocarbons, solvents, 444, 617  
 —, condensation with alkyl chlorides, 1132

- Hydrogenated methylrubber, properties of, 1096  
 Hydrogenated naphthalenes, condensation with aldehydes, 265  
 Hydrogenated petroleum hydrocarbons, solvents, 973  
 Hydrogenated phenols, solvents, 444, 456  
 Hydrogenated phthalides, plasticizers, 120  
 Hydrogenated rubber, use with lubricating greases, 249  
 Hydrogenated syntans, preparation, 419  
 Hydrogenated tung oil, polymerized, uses of, 1217, 1218  
 Hydrogenation, electrolytic, of sulphite liquor resins, 754  
 —, of abietic acid, 807  
 —, of alkali-digested cotton, 750  
 —, of animal oils, 636  
 —, of aromatic hydrocarbons, 268  
 —, of asphaltenes, 205  
 —, of balata and gutta-percha, 1096  
 —, of castor oil, 1221  
 —, of coal, 221, 275  
 —, of cumarone dibromide, 94  
 —, of cumarone resins, 119  
 —, of divinylacetylene, 154  
 —, of furfural, 518, 519  
 —, of indene, 97, 105  
 —, of mandelic acid, 1003  
 —, of para-indene resins, 119  
 —, of petroleum oil, 221  
 —, of phenol-aldehyde resins, 307  
 —, of polycyclopentadienes, 186, 188  
 —, of polydimethyleneurea, 580  
 —, of polystyrene, 237, 249  
 —, of rosin, 769  
 —, of rosin esters, 807  
 —, of rubber, 1095, 1096  
 —, of vegetable oils, 636  
 —, of vinylacetylene polymers, 160  
 Hydrogen bromide, reaction with acetylene, 1037  
 —, — acetylene polymers, 142  
 —, — rubber, 1114  
 —, — vinylacetylene, 149  
 Hydrogen-carbon monoxide reaction, resins from, 1255  
 Hydrogen chloride, action on diphenylmethyl ethyl ether, 1158  
 —, — indene, 98  
 —, — vinyl esters, 1032  
 —, catalyst, benzene-formaldehyde condensation, 265  
 —, — benzoyl cyanide-resorcinol reaction, 378  
 —, — condensation of benzyl chloride and methyl-naphthalene, 1182  
 —, — cyclohexanone-formaldehyde reaction, 559  
 —, — formaldehyde-methylene acetone reaction, 550  
 —, — hydrolysis of vinyl acetate, 1055  
 —, — preparation of diglycerol, 995  
 —, — polymerization of ethyl itaconate, 1085  
 —, — vinyl ester-aldehyde reaction, 1064  
 —, effect on chlororubber oil varnish, 1123  
 —, — polycyclopentadiene, 188  
 —, — rosin ester formation, 794, 795  
 —, — reaction with acetylene, 1035, 1036, 1037  
 —, — acetylene polymers, 142  
 —, — carbon suboxide, 1012  
 —, — cyclohexene, 167  
 —, — glycerol, 1176  
 —, — indole, 748  
 —, — rubber, 1112, 1113  
 —, — vinylacetylene, 149, 154  
 —, — vulcanized rubber, 1116  
 —, removal from chlororubber, 1110, 1111  
 —, — rubber hydrochloride, 1112, 1116  
 Hydrogen chloride-chlorine mixtures, action on rubber, 1113  
 Hydrogen cyanide, polymerization, 731  
 —, reaction with acetylene, 1070  
 Hydrogen fluoride, action on indene, 98, 102  
 —, catalyst, polymerization of cumarone, 117  
 —, — phenol-sulphur resins, 1191  
 —, — polymerization of olefins, 166  
 —, reaction with rubber, 1112, 1113  
 Hydrogen halides, reaction with gutta-percha, 1115  
 —, — rubber, 1105  
 —, removal from gutta-percha hydrohalide, 1115  
 —, use, alkylation of polyvinyl alcohol, 1067  
 Hydrogen iodide, action on cumarone, 94  
 —, reaction with rubber, 1114  
 Hydrogen ion concentration, change, during urea-formaldehyde reaction, 612  
 —, control by organic bases, 613  
 —, — magnesium carbonate, 612  
 —, control of, urea-formaldehyde reaction, 631  
 —, — phenol-aldehyde reaction, 352, 353  
 —, effect on dicyanodiamide-formaldehyde reaction, 680  
 —, — gelatinization of silicic acid, 1235  
 —, — phenol-aldehyde resins, 352, 353, 439, 440  
 —, — polymerization of acetylene, 149  
 —, — polymerization of diolefins, 178, 179  
 Hydrogen peroxide, action on aromatic hydrocarbons, 269  
 —, — anisole, 271  
 —, — films of acetylene polymers, 154  
 —, — magnesiymethylketole, 743  
 —, bleaching agent for resins, 339  
 —, catalyst, polymerization of acrylic acid nitrile, 1075  
 —, — diolefins, 180  
 —, — methyl acrylate, 1076, 1079  
 —, — styrene, 240, 245  
 —, — vinyl bromide, 1037  
 —, — phenol-aldehyde reaction, 416  
 —, — urea-formaldehyde reaction, 591  
 —, coloring phenol-aldehyde resins with, 442  
 —, from rubber ozonide, 1088  
 —, oxidative degradation of urea resin by, 586  
 —, removal of free formaldehyde by, 598  
 —, resin with acetaldehyde, 495  
 Hydrogen persulphide, reaction with benzaldehyde, 1182  
 Hydrogen selenide, reaction with benzaldehyde, 1180  
 Hydrogen sulphide, action on films of acetylene polymers, 153  
 —, — sulphite liquor, 754  
 —, — wash oils, 122  
 —, catalyst, drying oil polymerization, 1228  
 —, — phenol-formaldehyde reaction, 345, 346, 349  
 —, condensation with aniline and formaldehyde, 1181  
 —, — formaldehyde and methyl amine, 1181  
 —, for removal of sulphuric acid from sludge, 228  
 —, hardening agents, urea-formaldehyde resins, 598  
 —, reaction with acetaldehyde, 1180  
 —, — acetylene, 275  
 —, — acrylic acid chloride polymers, 1075  
 —, — acrylonitrile polymers, 1075  
 —, — aromatic aldehydes, 1180  
 —, —  $\beta$ -chlorovinylchloroarsine, 1012  
 —, — cyanamide, 681  
 —, — dicyanodiamide, 681  
 —, — formaldehyde, 1179  
 —, — furfural, 1180, 1181  
 —, — furfuralamide, 538  
 —, removal by p-nitroso compounds, 652  
 —, removal of free formaldehyde by, 599  
 Hydro-gutta-percha, preparation of, 1098  
 Hydrolysis, of carbanate, 571  
 —, of castor oil, 1221, 1222  
 —, of  $\omega$ -chlorotolyl carbonate, 294  
 —, of cumarone, 94  
 —, of ethylene chlorohydrin, 356  
 —, of ethylene cyanohydrin, 1070  
 —, of  $\beta$ -furfuralamides, 570  
 —, of  $\gamma$ -hydroxypropoxyacetic lactone, 1002  
 —, of lactic anhydride, 1003  
 —, of monochloroethylene, 1054  
 —, of ozonide of isoeugenol, 262  
 —, of phenol-formaldehyde resin, 307  
 —, of polyacrylic acid derivatives, 1069  
 —, of polyacrylonitrile, 1072  
 —, of polyamide of  $\epsilon$ -aminocaproic acid, 999  
 —, of polycinnamic esters, 1063  
 —, of polyvinyl esters, 1064-1067, 1069, 1063, 1069, 1070

- Hydrolysis, of polyvinyl halides, 1056  
 —, of proteins, 63, 69  
 —, of silk, 69  
 —, of wool, 68, 69  
 Hydrolytic degradation, of polyesters, 999  
 Hydrolytic products, from proteins, 66  
 Hydrolyzed wood, reaction with furfural, 749  
 Hydrometer floats, chloronaphthalene in, 1154  
 Hydrophenylfurfuryl alcohol, from furfural, 519  
 Hydrophilic colloids, in urea resin, 587, 630  
 Hydrophilic resins, from aryl sulphonamido carboxylic acid amides, 715  
 Hydrophilic sol, conversion to hydrophobic, 596  
 Hydrophilic stage, of urea resins, 630  
 Hydrophilic urea resin colloid, 565  
 Hydrophobe, urea resin, 630  
 Hydrophobe resin, preparation, 325, 326  
 Hydrophobic sol, conversion to hydrophilic, 596  
 Hydro pneumatic accumulator, use of, 1309  
 Hydroquinol, reaction with *o*-sulphobenzoic anhydride, 723  
 Hydroquinolsulphonaphthalein, from hydroquinol, 723  
 Hydroquinone, inhibitor, polymerization of acrylic acid, 1071  
 —, —, polymerization of diolefins, 180  
 —, —, polymerization of styrene, 242  
 —, —, polymerization of sulphones, 1178  
 —, oxidation inhibitor in nitrocellulose films, 823  
 —, reaction with acetylene, 333  
 —, —, furfural, 525  
 Hydroquinone dimethyl ether, 1157  
 Hydrorubber, comparison with polyisobutylene, 167  
 —, in lubricating oils, 1097  
 —, preparation of, 1095, 1096  
 —, properties of, 1095, 1096  
 —, pyrolysis of, 1096  
 —, specific viscosity of, 74  
 —, uses of, 1096, 1097  
 Hydrosilicates, catalyst, Friedel-Crafts reaction, 1137  
 —, —, polymerization of olefins, 166  
 —, —, polymerization of vinyl ethers, 1011  
 Hydrosols, use of polyvinyl alcohol in, 1058  
 Hydrotropic salts, use of, 338  
 Hydrotropism, effect of, resin precipitation, 337  
 Hydroxyacanthine, oxidation of, 745  
 Hydroxy acids, by oxidation of hydrocarbons, 1233  
 —, from oxidized petroleum, 911  
 —, in shellac, 1004, 1005  
 —, in shellac substitutes, 1139  
 —, polyesters from, 999, 1000, 1001  
 —, reaction with lactones, 1002  
 —, sulphonation of, 910  
 $\alpha$ -Hydroxy acids, lactides from, 1000  
 $\gamma$ -Hydroxy acids, lactones from, 1000  
 $\delta$ -Hydroxy acids, lactones from, 1000  
 Hydroxyaldehydes, polymerization of, 506, 507  
 Hydroxyalkyl esters of abietic acid, from colophony, 797  
 —, softening agents for lacquers, 823  
 Hydroxyalkyl esters of drying oil acids, reaction with resin acids, 803  
 3-Hydroxy-3'-aminobenzenesulphone, preparation of, 1190  
 Hydroxyaromatic alcohols, reaction with cyclic ethers, 431  
 —, reaction with polyhydric alcohols, 431  
 Hydroxyarylmethane, condensation with aldehydes, 389  
 4-Hydroxy-1-azidoacetylbenzene, resins from, 737  
*o*-Hydroxyazo dyes, salts of, use, 1250, 1251  
 3-Hydroxy-6-benzalaminotoluene, reaction with sulphur, 1196  
*m*-Hydroxybenzaldehyde, condensation with acetone, 563  
 Hydroxybenzaldehyde, in Cannizzaro reaction, 293  
 —, preparation, 299  
 —, reaction with phenols, 383  
*o*-Hydroxybenzenethiol, formation of, 1189  
*m*-Hydroxybenzoic acid, oxidation of, 375  
 —, reaction with thionyl chloride, 1187, 1188  
*p*-Hydroxybenzoic acid, dehydration of, 378  
 —, resins from, 375  
 Hydroxybenzoic-acid resins, films from, 378, 379  
 —, preparation, 378  
 Hydroxybenzoic acids, condensation with hexamethylenetetramine, 309, 374  
 —, reaction with iodine, 378  
*o*-Hydroxybenzophenone, 1135  
*p*-Hydroxybenzophenone, resinification of, 555  
 Hydroxybenzyl alcohol, action of alkali on, 293  
 —, condensation with formalglycerol, 447  
 —, ethers of, 1003  
 —, from chlorotolyl carbonates, 1141  
 —, from cresol and formaldehyde, 1044  
 —, from phenol and aldehyde, 432  
 —, from salicylic acid, 277  
 —, polymerization of, 349  
 —, plastic masses from, 292  
 —, reaction with aldoses, 760  
 —, reaction with allyl bromide, 1044  
 —, reaction with hexamethylenetetraminetriphenol, 332, 333  
 —, reaction with naphthalenesulphonic acid, 419  
 —, reaction with vinyl bromide, 1044  
 —, resins from, 287, 333  
 —, use with cellulose acetate, 432  
*o*-Hydroxybenzyl alcohol, formation of, 281  
 —, saliretin from, 291  
*p*-Hydroxybenzyl alcohol, formation of, 281, 292  
 —, resinification of, 281  
 Hydroxybenzyl alcohol resin, as adhesive, 373  
*o*-Hydroxybiphenyl, use in alkyl resins, 930  
 Hydroxybiphenyls, as preservatives, 196  
 —, condensation with formaldehyde, 408, 409, 412  
 —, from chlorobiphenyls, 409, 412, 413  
 —, reaction with lead oxide, 273  
 Hydroxybromide, of indene, 99  
*p*-Hydroxy-ter-butylbenzenesulphonic acid, reaction with formaldehyde, 419  
 $\beta$ -Hydroxybutyraldehyde, *see also* Aldol  
 —, formation, 489  
 $\alpha$ -Hydroxybutyric acid, dehydration of, 1080  
 4-Hydroxy-3-carbethoxy-4-pentanone, preparation of, 546  
 —, reaction with diethylamine, 546  
 Hydroxycarboxylic acid-boron trifluoride complex, polymerization catalyst, 119  
 Hydroxycarboxylic acids, esters of, condensation with aldehydes, 374  
 —, esters of, reaction with silicic acid, 1237  
 —, reaction with methylolureas, 667  
*c*-Hydroxycaproic acid, dimer, formation of, 1002  
 —, polyester of, 1002  
 —, preparation of, 1001  
*c*-Hydroxycaproic lactone, formation of, 1002  
 Hydroxychloride, of indene, 98  
*o*-Hydroxy- $\beta$ -chlorostyrene, cumarone from, 93  
 Hydroxycyclohexanecarboxylic acid, 1139  
 $\omega$ -Hydroxydecanoic acid, molecular weight determination of, 1002  
 —, polyesters from, 999, 1002  
 Hydroxydiphenylamine, catalyst, phenol-formaldehyde reaction, 346, 347  
 7-Hydroxy-2,4-diphenylbenzopyrylium chloride, preparation, 295  
*p*-Hydroxydiphenylmethane, 1133  
 Hydroxydiphenyl sulphide, reaction with iodine, 1136  
*p*-Hydroxydiphenyl sulphide, formation of, 1186, 1187  
 —, toxicity of, 1187  
 Hydroxyesters, reactions with dimethylolurea, 646  
 $\beta$ -Hydroxyethyl adipate, preparation, 892  
 Hydroxyethylamine, condensation with aldehydes, 705  
 Hydroxyethyl ethyl phthalate, plasticizer, 897  
 Hydroxy fatty acid esters, modifiers, urea-aldehyde resins, 669  
 Hydroxy fatty acids, synthesis of, 1003  
 Hydroxyamine, catalyst, phenol-formaldehyde reaction, 346  
 Hydroxyamine hydrochloride, catalyst, phenol-furfural reaction, 527  
 Hydroxylated ethers, of glycerol, in alkyl resins, 999  
 Hydroxylated fats, from chlorinated fish oils, 1225  
 Hydroxylated fatty oil, in lacquers, 965

Hydroxylated solvents, urea-formaldehyde condensation in, 636  
 Hydroxylated vinyl compounds, sensitivity to alkalis, 1007  
 Hydroxyl groups, activity of, in glycerol condensations, 61, 866  
 —, effect, on velocity of phenol-aldehyde condensation, 371  
 Hydroxyl number, 1261  
 Hydroxyl value, of polyglycerols, 995  
 $\alpha$ -Hydroxylepine, condensation with aromatic aldehydes, 745  
 4-Hydroxy-3-methoxypropenol, electrolytic oxidation of, 272  
 4-Hydroxy-3-methoxystyrene, preparation of, 256  
 2-Hydroxy-3-methylbenzoic acid, 1133  
 Hydroxymethylene-methyl-*n*-propyl ketone, polymerization of, 551  
 Hydroxymethyl ether, of cresol, condensation with formaldehyde, 400  
 3-Hydroxy-2-methylindole, resinification, 743  
 $\beta,\beta$ -bis-(4-Hydroxy-3-methylphenyl) propane, reaction with formaldehyde, 377  
 bis-(4-Hydroxy-3-methylphenyl) selenide, preparation, 1193  
 $\beta$ -Hydroxy methyl propionate, in linseed oil lacquer, 823  
 $\beta$ -Hydroxynaphthaldehyde, condensation with aniline, 705  
 2,3-Hydroxynaphthoic acid, glyceride oils modified with, 1227  
 Hydroxynaphthoic acids, film-hardening agents, 633  
 —, modifiers, urea-aldehyde resins, 678  
 Hydroxy- $\beta$ -naphthol alcohols, resins from, 333  
 $\alpha$ -Hydroxy-*o*-naphthoylbenzoic acid, condensation with phenols, 376  
 Hydroxynaphthylmethylsulphonic acid, preparation, 352  
 1-Hydroxy-octane-3,7-dione, preparation, 550  
 10-Hydroxy-oleic acid, ketostearic acid from, 1222  
 $\omega$ -Hydroxy-pentadecanoic acid, polyesters of, 872  
 bis-*p*-Hydroxyphenyl-1,1-cyclohexane, preparation of, 390  
 2-Hydroxy-3-phenylindazole, resinification, 736  
*p*-Hydroxyphenylphenoxymethane, preparation, 360  
 —, reaction with formaldehyde, 301  
*p*-Hydroxyphenylpyrindone, methylation of, 738  
 bis-*p*-Hydroxyphenyl sulphide, preparation of, 1133  
 Hydroxyphenyl sulphides, germicides from, 1186  
*p*-Hydroxyphenyltrichloromethylcarbinol, preparation, 294  
 $\beta$ -Hydroxypropionic acid, acrylic acid from, 1069, 1070  
 $\beta$ -Hydroxypropionitrile, acrylic esters from, 1074  
 $\gamma$ -Hydroxypropoxyacetic acid, lactone from, 1001, 1002  
 $\gamma$ -Hydroxypropoxyacetic lactone, hydrolysis of, 1002  
 3-Hydroxy-1,2-propylene sulphide, incorporation with rayon, 1177  
 $\alpha$ -( $\beta$ -Hydroxypropyl)- $\gamma$ -phenyl- $\gamma$ -butyrolactone, resinification, 738  
 bis- $\beta$ -Hydroxypropyl sulphide, reaction with phosphorus trichloride, 1179  
 Hydroxypropyl vinyl ether, preparation of, 1009, 1010  
 $\gamma$ -Hydroxyquinolines, condensation with aromatic aldehydes, 745  
 Hydroxyquinoline, catalyst, phenol-formaldehyde reaction, 346, 347  
 Hydroxystearic acids, shellac-like resin from, 1006  
 12-Hydroxystearin, from castor oil, 1221  
 $\alpha$ -Hydroxystyrene, resin from, 200  
 4'-Hydroxy- $\theta$ -styrylanthium chloride, resinification, 241  
 Hydroxytoluic acid, condensation with aldehydes, 374  
 $\beta$ -Hydroxytrimethylene sulphide, modifier, urea-aldehyde resins, 684  
 Hydroxytolquinone, from *asym-m*-xyldine, 732  
 Hypochlorites, in rosin oxidation, 774  
 Hypochlorites, reaction with rubber, 1094, 1114

Hypochlorous acid, effect on latex, 1113  
 —, reaction with oleone, 551  
 —, — rosin, 804  
 —, — rubber, 1113  
 Hypophosphorous acid, bleaching of phenol-aldehyde resins with, 429  
 Hyrax, composition of, 1202

## I

Ice cream, use of polyvinyl alcohol, 1068  
 Iceland moss, see Lichenin  
 Ideal varnish, nature of, 36  
 Illuminating gas, purification of resins with, 335  
 Illuminating materials, cuprene as absorbent for, 146  
 Imide, by polymerization of acrylic acid amide, 1074  
 Imides, condensation with aldehydes, 708  
 Imitation marble, resin, preparation of, 468  
 Immersion tests for laminated materials, 1343  
 Impact machine, simple beam, 1343  
 Impact-molding material, from phenolic resin, 462  
 Impact press, use in cold-molding operation, 1312  
 Impact strength, of laminated materials, 1342  
 —, of molding materials, determination, 1358  
 Impervious coating, from phenol resin with rubber, 450  
 Importation, of phenol, into United States, 359  
 Impregnant, chloroprene as, 159  
 —, chlororubber, 1121, 1127, 1128  
 —, cresylic acid-formaldehyde resin in tung oil, 365  
 —, for cloth, phenol-formaldehyde resin as, 533  
 —, for fabrics, Toron, 1200  
 —, for paper, furfural-phenol resin as, 533  
 —, for stone, vulcanized asphalt, 1203  
 —, for textiles, from stearin pitch, 1203  
 —, for wood, furfural-chloronaphthalene resin as, 533  
 — from rubber, 1097  
 —, urea-aldehyde resin, 671  
 —, vinylacetylene as, 150  
 Impregnants, benzal chloride resins as, 1134  
 —, chloronaphthalenes as, 1133  
 —, for wood, 1133  
 —, from alkyl halides and tar oil, 1131  
 —, from the butadienol esters, 152  
 —, from modified urea-aldehyde resin, 685  
 —, from phthalic anhydride-modified urea-aldehyde resin, 683  
 —, from  $\alpha$ -polychloroprene, 159  
 —, from polymers of 1,3-dienes, 185  
 —, from polymers of vinyl ethinyl carbinols, 151  
 —, from shellac, 24  
 —, from sulphurized products, 1210  
 —, natural resins used as, 18  
 —, partially hydrolyzed polyvinyl esters, 1059  
 —, phenol-aldehyde resins as, 362  
 —, phenolic resins, preparation of, 481  
 —, phenol-sulphur resins as, 1193  
 —, synthetic resins, 1245, 1246, 1247, 1248, 1249  
 —, tests for non-volatile matter in, 1363  
 —, urea-furfural resins, 669, 670  
 —, urea resins, 565  
 —, waxes, 1245  
 Impregnated asbestos sheets, use of, 474  
 Impregnated bodies, with phenolic resins, 481-493  
 Impregnated canvas, uses of, 471  
 Impregnated wood, properties, 481  
 Impregnating agent, cashew-shell oil, 1232  
 —, for paper, ester gum in, 828  
 —, from rubber, 1100  
 —, from sulphurized Japanese lacquer, 1206  
 —, from vulcanized castor oil-petroleum pitch mixture, 1204  
 —, resin from naphthalene as, 206  
 Impregnating agents, from polymerised acrylic esters, 1077  
 —, from vinyl resins, 1060  
 —, polyvinyl ethers as, 1011  
 —, urea resins as, 630, 631  
 Impregnating fabrics, use of alkyl resins, 905  
 Impregnating materials, nitrated rubber for, 1064  
 —, from coal-tar pitch dyes, 376  
 Impregnation, by injection, 1235  
 —, of cellulosic material, method, 1245

- Impregnation, of fabrics, with phenol oil-formaldehyde resins, 406  
 —, of wood with Aroclor resins, 1147  
 —, with alkyd resins, 891  
 —, with cresol-aldehyde resins, 423  
 —, with sulphur, 1167  
 Impregnator for fibrous material, furyl alcohol resin as, 522  
 Impurities, in cumarone resins, 125  
 —, in resin, removal, 767  
 Incandescent-lamp filaments, from phenol-aldehyde resin, 285  
 Incorporating fillers, method, 1316  
 Indamine, catalyst, for phenol-formaldehyde reaction, 347, 348  
 Indane, see hydrindene.  
 Indazole-1-carboxylic acid esters, pyrolysis, 736  
 Indelible printing ink, cumarone resin with, 140  
 Indene, action of air on, 98, 101  
 —, aluminum chloride on, 103  
 —, antimony pentachloride on, 102, 103  
 —, boron trichloride on, 102  
 —, bromine on, 100  
 —, ethyl oxalate on, 98  
 —, glacial acetic acid on, 102  
 —, halogens on, 97  
 —, hydrogen chloride on, 98, 102  
 —, hydrogen fluoride on, 98, 102  
 —, hydrogen halides on, 98  
 —, iodine on, 102  
 —, nitrous acid on, 98  
 —, oxygen on, 103  
 —, oxygenated derivatives on, 103  
 —, perbenzoic acid on, 103  
 —, phenyldiazonium fluoborate on, 103  
 —, phosphoric acid on, 102  
 —, picric acid on, 99  
 —, potassium permanganate on, 98  
 —, sodamide on, 98  
 —, stannic chloride on, 102, 103  
 —, sulphuric acid on, 92, 100, 101  
 —, sunlight on, 101  
 —, titanium tetrachloride on, 102  
 —, ultraviolet light on, 101  
 —, zinc chloride on, 102  
 —, as plasticiser in alkyd resin coatings, 964  
 —, bromination of, 97, 98, 102  
 —, by cracking, 201  
 —, by pyrolysis, 96  
 —, chloroindane from, 98  
 —, condensation with formaldehyde, 265  
 —, conditions of polymerisation, 100  
 —, 1,2-dihydroxyindane from, 98  
 —, diindene from, 101  
 —, dimerisation of, 102  
 —, effect of heat on, 100  
 —, light on, 100  
 —, pressure on polymerisation of, 49  
 —, sulphuric acid on, 167  
 —, ethyl indeneoxalate from, 98  
 —, from acetylene-hydrogen mixtures, 96  
 —, from carburetted water gas, 96, 97  
 —, from coal gas, 97  
 —, from coal tar, 96, 97, 99  
 —, from crude naphtha, 99  
 —, from drip oil, 97  
 —, from natural gas, 96  
 —, from phenols, 96  
 —, from polyindene, 104  
 —, from primary tars, 96  
 —, from tar oils, 99  
 —, gum from, 103  
 —, heat effect of polymerisation, 95  
 —, hetero-polymerisation of, 100  
 —, homophthalic acid from, 98  
 —, homo-polymerisation of, 92, 100  
 —, hydrindene from, 97  
 —, hydrogenation of, 97, 105  
 —, hydroxybromides of, 99  
 —, identification of, 97  
 —, influence of concentrations of sulphuric acid on, 101  
 —, iodoindanes from, 102  
 —, mechanism of polymerisation of, 104  
 —, metaindane from, 101  
 —, nitroindane from, 98  
 —, indene, oxidation of, 100  
 —, paraindene from, 101  
 —, photopolymerization of, 101  
 —, physical properties of, 96  
 —, polyindenes from, 100  
 —, polymerization of, 100, 257, 258  
 —, by stannic chloride, 990  
 —, unimolecular reaction, 104  
 —, polymerized, 123  
 —, bromine absorption of, 103  
 —, dielectric constants of, 103  
 —, effect in cumarone resins, 106  
 —, fractional precipitation of, 101  
 —, reaction with benzaldehyde, 98  
 —, maleic anhydride, 895  
 —, nitrogen peroxide, 727  
 —, tin tetrachloride, 100  
 —, reduction of, 97  
 —, relation to cumarone, 92  
 —, removal from naphtha, 106  
 —, resemblance to rubber, 1101  
 —, resinous polymers from, 105  
 —, resin with paraformaldehyde, 265  
 —, separation from cumarone, 99  
 —, styrene, 99  
 —, similarity to cyclopentadiene, 92  
 —, styrene, 92, 100  
 —, sodium indene from, 99  
 —, solvent, alkyd resins, 880  
 —, structure of, 92  
 —, synthesis of, 97  
 —, tetraindene from, 100  
 —, tetramer of, 101  
 —, thermopolymerization of, 100  
 Indene-cumarone resins, analytical scheme, 1257  
 —, constituents, 1257  
 —, identification, 1257  
 —, properties, 1257  
 —, uses, 1257  
 —, varnish from, 131  
 Indene dibromide, from indene, 97  
 —, indene hydroxybromide from, 97  
 Indene dichloride, from indene, 98  
 Indene-formaldehyde condensation product, character of, 266  
 —, similarity to drying oil, 266  
 Indene hydroxybromide, from indene dibromide, 97  
 Indene hydroxychloride, from indene dichloride, 98  
 Indene-phenol ratio, effect of, in cumarone resins, 119  
 Indene picrate, decomposition of, 99  
 —, from indene, 99  
 Indene polymerization, aryl diazonium fluoborate catalyst in, 176  
 —, exothermic nature of, 109  
 —, use of acetic acid in, 180  
 —, acetone in, 180  
 —, arsenious acid in, 180  
 —, iodine in, 180  
 —, phenols in, 180  
 —, reducing agents in, 180, 181  
 —, sulphur in, 180  
 —, x-ray studies of, 50  
 Indene polymers, properties, 100, 101, 102, 103, 104, 105  
 Indene resins, use of, with coal-tar bitumen, 360  
 —, x-ray patterns of, 80, 81, 82  
 —, indenes, compatible, chlororubber, 1119  
 Index, Trade Names, 1380  
 Index of refraction, change during reaction of phenol and formaldehyde, 313  
 Indigo blue, oxidation, 744  
 Indigoid dyes, use, with phenol-aldehyde resins, 443  
 Indole, from acetylene and aniline, 704  
 —, reaction with diindole hydrochloride, 743  
 —, hydrogen chloride, 743  
 —, metaphosphoric acid, 743  
 —, resinification with hydrochloric acid, 743  
 —, resins from, 743, 745  
 Indolymagnesium iodide, reaction with chloroacetonitrile, 743  
 —, ethyl acetate, 743  
 —, resins from, 743

- Indophenol, catalyst, for phenol-formaldehyde reaction, 347, 348  
 —, color test, 1259  
 Inductive capacity, of chloronaphthalene waxes, 1182  
 Inert gas, polymerization of fatty oils in, 1228  
 —, polymerisation of glycerols with, 995  
 Inert gases, effect of, separation of styrene, 254  
 Inflammability, of varnish films, 19  
 Infusibility, of molded objects, 22  
 Infusible alkyd resin, influence of heat on, 864  
 Infusible phenol-formaldehyde resin, 297  
 Infusible products from starch, 760  
 Infusible resins, conversion to fusible resins, 692  
 —, formation of, 11  
 —, from fusible resins, 693  
 Infusible transparent resins, phenol-aldehyde, with excess of formaldehyde, 323  
 Infusional earth, effect of, in synthetic rubber, 198  
 Inhibitor, anthracene, polymerization of styrene, 242  
 —, benzoquinone, polymerization of styrene, 242  
 —, cresol, polymerization of styrene, 242  
 —, eugenol, 408  
 —, hydroquinone, polymerization of styrene, 242  
 —,  $\alpha$ -naphthol, 408  
 —, pickling, urea resin as, 649  
 —, pyrogallol, polymerization of styrene, 242  
 —, sulphur, polymerization of styrene, 242  
 —, trinitrobenzene, polymerization of styrene, 242  
 Inhibitors, for gum, 222, 223, 224  
 Inhibitors, polymerization of furylethylene, 243  
 —, —, polymerization of styrene, 242  
 —, use of, with styrene, 242  
 Injection, of resins, into fibrous materials, 1325  
 Injection mold, operation of, 1294  
 Injection molding, 1321, 1322, 1323  
 —, advantages of, 1323, 1325  
 —, mottled effects, 1325  
 —, of reactive resins, 1324, 1325  
 —, of thermoplastic materials, 1324  
 —, types of presses, 1325  
 Inks, alkyd resins in, 979  
 —, colored phenol resins in, 453  
 —, from polyvinyl alcohol, 1060  
 —, intaglio, from synthetic resins, 1260  
 —, non-drying, cumarone resin in, 140  
 —, printing, cumarone resins in, 123, 139  
 —, —, from tall oil, 755  
 —, —, from terpenes, 781  
 —, —, from wood oil, 781  
 —, —, metallic soaps in, 790  
 —, silica black in, 1235  
 —, transfer, cumarone resin in, 140  
 Inorganic acid chlorides, condensing agents, 289, 290  
 Inorganic acids, catalysts, condensation, urea and formaldehyde, 616  
 —, —, curing, cellulose-urea resin compositions, 622  
 —, in varnishes, prevention of yellowing, 1378  
 Inorganic compounds, sulphonamide-aldehyde resins, binder, 721  
 Inorganic fillers for phenol-aldehyde molding powders, 458-461  
 Inorganic halides, catalysts, polymerization of tung oil, 1219  
 —, mechanism of polymerizing action, 50, 51  
 Inorganic resins, insulation from, 1240  
 —, varnishes from, 1240  
 Insect adhesives, from tall oil, 756  
 Insecticide, factice in, 1212  
 —, from sulphur and rosin, 1164  
 Insecticide carrier, silica black in, 1235  
 Inserts, adapting preforms to, 1319  
 —, in molded articles, 1296  
 —, machining of, 1331  
 —, metal, use, injection molding, 1325  
 —, placing in mold, 1330  
 —, types of, 1296  
 Insoluble infusible resins, from cresol-hexamethylenetetramine reaction, 329  
 —, from phenol and formaldehyde, 291, 297, 317, 318, 319  
 —, from phenol-hexamethylenetetramine reaction, 329  
 —, from soluble fusible resins, 345  
 —, use of term, 315  
 Insoluble polymers from benzyl chloride, 1120  
 Insoluble resins, soluble resins from, 340, 341  
 Inspection, of moldings, 1331  
 Instability, of methyl rubber, 178  
 Insulating agent, from sulphurized Japanese lacquer, 1206  
 Insulating capacity, of aniline-formaldehyde resins, 692  
 Insulating characteristics of cumarone resin, 134  
 Insulating coating, alkyd resins in, 905  
 —, from rubber, 1092, 1098  
 —, resin-modified cellulose lacquers, 447, 448  
 Insulating composition, cumarone resin and tung oil, 133, 135  
 —, from chlorobiphenyl, 1151  
 Insulating compositions, 778  
 —, from sulphur and cumarone resin, 1162  
 —, phenol-formaldehyde resins with glycerol-phthalic anhydride resins in, 530  
 Insulating compound, from gutta-percha, 1091  
 —, of linseed oil and stearin pitch, 1203  
 —, rubber in, 1091  
 Insulating compounds, Aroclors in, 1150  
 —, cumarone resin in, 133  
 Insulating material, acetaldehyde resin in, 495  
 —, composition of, 828  
 —, electrical, from tar distillates, 273  
 —, ethyl abietate in, 828  
 —, from cashew-shell oil, 1232  
 —, from cumarone resin, 112, 1243  
 —, from formolites, 213  
 —, from urea resins, 625, 626  
 —, magnetic, preparation of, 1249  
 —, nitrated rubber, 1094  
 Insulating materials, amine-aldehyde resins, 696  
 —, from shellac, 24  
 —, from sulphonamide-aldehyde resins, 721, 722  
 —, from tall oil, 757  
 —, modified urea-aldehyde resin, 684  
 —, urea resins, 623  
 Insulating paper, from chlororubber, 1126  
 Insulating properties, of phenol-furfural-alkyd resin compositions, 939  
 —, of polystyrenes, 249  
 Insulating varnish, gum acroides in, 819  
 Insulating varnishes, from modified phenol-aldehyde resins, 439  
 —, from phenol-resins, 450  
 —, furfural-ketone resins in, 538  
 Insulation, chloronaphthalene in, 1152  
 —, electrical, chlorinated cumarone compounds in, 139  
 —, —, cold-molded, 1288  
 —, —, cumarone resin in, 140  
 —, —, from leather-modified phenol-aldehyde resin, 418  
 —, —, from phenol-furfural resin, 532  
 —, —, from vinyl resins, 1051  
 —, —, urea in, 566  
 —, flame-proof, cold-molded, 1287  
 —, fluorinated compounds in, 1151  
 —, for cables, butadiene polymerisation product and ethylene oxide-abietic ester in, 828  
 —, from inorganic resins, 1240  
 —, from rubber and sulphonic acids, 1098  
 —, from rubber-sulphonyl chloride product, 1098  
 —, furfural-phenol resin in, 523  
 —, heat, from leather-modified phenol-aldehyde resin, 418  
 —, metallic soaps in, 790  
 —, phenol-carbohydrate resins in, 759  
 —, phenol-furfural-p-aminophenol resin in, 531  
 —, phenol-resin impregnated fabric, 471, 474  
 —, submarine cable, 1091, 1096  
 Insulator, Bakelite, 482  
 —, electrical, polystyrene resin, 248  
 —, marble, by polystyrene treatment, 251  
 Insulator qualities, determination of, 1349  
 Insulators, aldehyde-amine resins, 710  
 —, electrical, 860  
 —, —, alkyd resins, 864  
 —, —, for tar oil hydrocarbon-acetone resin, 275  
 —, from alkyd resins, 877  
 —, from chlorinated hydrocarbons, 220  
 —, from mica and polyhydric alcohol-dicarboxylic acid resin, 963

- Iodine number, of cumarone resin, 125
- , of tung oil, reduction of, 1217
  - , quantitative determination, 1256, 1260, 1261
  - , use of, control of cooking of oils, 1226, 1227
- Iodine value, of cashew-shell oil, 1229
- , of resin from cracked-gasoline, 191
- $\alpha$ -Iodoacetaldehyde, polymerisation of, 606
- $\alpha$ -Iodobromobenzene, reaction with copper, 1142
- Iodoindene, from indene, 102
- Iodoform, in light-sensitive coatings, 699
- , modifier, phenol-aldehyde resins, 681
- Iodoindanes from indene, 102
- Iodophenol, formation of, 1191
- $\beta$ -Iodopropionic acid, acrylic acid from, 1070
- , reaction with alcoholic potash, 1070
  - , —, lead oxide, 1070
  - , —, sodium carbonate, 1070
- bis-3-Iodopropyl sulphide, decomposition, 1179
- Ionic micelles, phenol formaldehyde resins as, 31
- $\beta$ -Ionone, fulvene of, resin from, 270
- Iron, action on petroleum tar, 217
- , —, catalyst, acetylene polymerisation, 143, 146
  - , —, acrolein formation, 994
  - , —, air-oxidation of phenol, 271
  - , —, ammonia-carbon monoxide reaction, 684
  - , —, chlorination of biphenyl, 1144
  - , —, —, naphthalene, 1151
  - , —, condensation, xylol chloride and naphthalene, 1131
  - , —, dechlorination, 220
  - , —, drying oil polymerization, 1228
  - , —, ester gum formation, 802
  - , —, formation of oily polymers of 1,3-dienes, 185
  - , —, oxidation of tar and tar oils, 273
  - , —, reaction, polyvinyl alcohol and haloethers, 1067
  - , —, rosin esterification, 799, 800
  - , —, effect on rosin, 772
  - , —, turpentine, 783
  - , —, filler, phenol-aldehyde molding powder, 459, 460
  - , —, hardening catalyst, alkyd resins, 981
  - , —, incorporation with montan wax, 211
  - , —, inhibitor, vinyl ester-aldehyde reaction, 1064
  - , —, oxidation catalyst, 209
  - , —, polymerization catalyst for furfural, 521
  - , —, removal of organic compounds of, from coal-tar fractions, 361
- Iron-bronze, inhibitor, polymerization, vinyl bromide, 1037
- Iron carbonate, modifier, phenol-aldehyde resins, 438
- , reaction with benzal chloride, 1134
- Iron carbonyl, catalyst, in polymerization of 1,3-dienes, 184
- Iron castings, use in making molds, 1297
- Iron chloride, catalyst, furfural-aniline reaction, 535
- , reaction with phenol resins, 310
- Iron halide, catalyst, polymerisation of 1,3-dienes, 183
- Iron monoalkyl phthalate, preparation, 930
- Iron naphthenates, 207
- Iron oleate, oxidation catalyst, 210
- Iron oxide, catalyst, acetylene polymerization, 146
- , —, condensation, acetone with carnauba wax and rape oil, 541
  - , —, dechlorination, 220
  - , —, polymerisation of ethylene oxide, 991
  - , —, preparation of styrene, 254
  - , —, dehydrogenating agent, 216
  - , —, filler for mica sheets, 933
  - , —, in cold-molding composition, 1286
  - , —, in rosin-biphenyl compositions, 1150
  - , —, modifier, phenol-aldehyde resins, 437, 438
  - , —, pigment, 1276
  - , —, chlororubber paint, 1120
  - , —, use of, 407
- Iron pipes, coated with chlororubber, 1131
- Iron powder, incorporation with urea resins, 623
- Iron pyromucate, polymerisation catalyst for furfural, 521
- Iron resinate, catalyst, oxidation of tall oil, 755
- Iron salts, neutralizing agents, 344
- , of alkyd resins, 946
- Iron-zinc foil, catalyst, polymerization, vinyl bromide, 1037
- Irish moss, use of, in emulsification, 945
- , with urea resin, 681
- Irradiation, effect on, polymerisation, 547
- , of cinnamic acid, 1088
  - , polymerisation of isopropenyl methyl ketone by, 551
- Irregular pieces, die casting of, 1296
- Irreversible gelation, 39
- , in glycerol phthalate resins, 869
- Irritant, skin, chloronaphthalenes as, 1152

- Isatin, condensation with benzaethyl ketone, 744  
 —, —, formaldehyde, 689  
 —, —, furfurylideneacetone, 744  
 —, —, methylcinnamylvinyl ketone, 744  
 —, from, indigo blue, 743  
 —, —, oxindole, 744  
 —, resinification, 744  
 Isatoid, from, isatin, 744  
 —, resinification, 744  
 Isatropic acids, structure of, 1084  
 Isoamylaniline, condensation with formaldehyde, 687  
 Isoamyl cinnamate, polymerization, 1082  
 Isoamyl pyromucate, from reaction of furfural and acetaldehyde, 619  
 Isobornyl chloride, reaction with formaldehyde, 515, 516  
 Isobutane, from heptanaphthene, 215  
 Isobutene, polymerization with aluminum chloride, 166  
*p*-Isobutenylaniline, from 2,2'-diaminodiphenylbutane, 732  
 —, polymerization of, 732  
 Isobutyl alcohol, reaction with phenol, 410  
 —, urea-formaldehyde condensation in, 637  
 Isobutylchlorourea, reaction with aldehydes, 574, 575  
 Isobutylene, action of silent electric discharge on, 165  
 —, —, sulphuric acid on, 167  
 —, effect of boron trifluoride on polymerization of, 166  
 —, —, floridin on polymerization of, 166  
 —, molecular weight of polymerized, 166  
 —, polymerization, 167  
 —, —, effect of temperature, 166  
 —, reaction of, with liquid sulphur dioxide, 167  
 —, resinous substances from, 165  
 Isobutylene-acetone, condensation, in presence of sodium hypobromite, 550  
 Isobutylene esters of phenylacrylic acid, polymerization, 1083  
 Isobutylene polymers, use of, as adhesives, 200  
 Isobutyl phthalate, plasticizer, polyvinyl acetal, 1082  
 2-Isobutylquinoline, resinification, 739  
 Isobutyraldehyde, polymerization of, 506, 507  
 —, reaction with furfural, 519  
 Isobutyric acid, use of, in alkyl resins, 906  
 Isobutyrylphthalimide, decomposition, thermal, 553  
 $\alpha$ -Isocacoutchouc, decomposition of, 1089  
 —, ozonide of, 1089  
 —, preparation of, 1089  
 Isocollod materials, containing fatty acids, heating in electrolytes, 1227  
 Isocollod theory, of polystyrol resins, 235  
 Isocolloids, nature of, 36, 37, 56  
 Isocrotonic acid, from crotonic acid, 1081  
 Isocyanates, reaction with dimethylketene, 553  
 Isocyanic acid, combination with ammonia, 569  
 Isodibromosuccinic anhydride, hardening agent, urea resins, 618  
 Isoeugenol, bromination of, 1154  
 —, effect of potassium ferrocyanide on resinification of, 262  
 —, —, toluene on resinification, 262  
 —, hydrolysis of ozonide of, 262  
 —, ozonolysis of, 262  
 —, polymerization, lead peroxide anode, 262  
 —, resins from, with caustic soda, 262  
 —, —, with sodium sulphate, 262  
 —, vanillin from, 262  
 Isoeugenol resinification, effect of methylation of phenolic group, 262  
 —, prevention of, 262  
 Isoeugenol-vanillin solution, electrolytic oxidation of, 262  
 Isoheptene oxide, preparation, 1254  
 —, resin from, 1254  
 4-Isobutenyl-*cis*- $\Delta^4$ -tetrahydropthalic anhydride, synthesis of, 843  
 Isolation of, compounds from phenol-formaldehyde condensation products, methods, 292  
 —, diindene, 103  
 Isolation of 2,6-methyl-*p*-cresol, 293  
 —,  $\alpha$ -polychloroprene, 156  
 —, resorcinol alcohols, 371  
 Isomeric butenes, alkylated phenols from octenes of, 411  
 Isomeric forms, of cinnamic acid, 1082  
 Isomerization, of tung oil, 923  
 —, in fused rosin, 766  
 Isomethyleugenol, resins by steam distillation, 261  
 —, varnish from, 261  
 Isomitosates, polymerization, 727  
 Isomitosates, polymerization, 727  
 Isophorone, reduction with, zinc amalgam and hydrochloric acid, 541  
 Isophthalaldehyde, condensation with, benzidine, 688  
 Isophthalic acid, use of, in alkyl resins, 925  
 Isoprene, attempt to prepare, 161  
 —, condensation with aromatic hydrocarbons, 193, 194  
 —, —, ketene, 554  
 —, co-polymerization with chloroprene, 157  
 —, —, monolefins, 192  
 —, dimetic, 173  
 —, dipentene from, 172, 1087  
 —, effect of electromagnetic fields, 176  
 —, —, heat, 172, 173, 175, 178  
 —, —, light on, 174  
 —, —, pressure on polymerization of, 49  
 —, —, silent electric discharge, 174  
 —, emulsification, 179, 180  
 —, estimation of, by diene reaction, 830  
 —, formation of, 1089  
 —, from acetone-vinyl bromide reaction, 1253  
 —, from acetylene, 177  
 —, from amyl alcohol, 177  
 —, from destructive distillation of rubber, 1089  
 —, from rubber, 1087  
 —, mechanism for thermal polymerization of, 170  
 —, monomeric form of rubber, 169  
 —, *g*-myrcene from, 172  
 —, ozonized, as catalyst in isoprene polymerization, 176  
 —, photopolymerization, effect of oxygen, 1020  
 —, polymerization, 169, 172, 173, 174, 175, 178, 179  
 —, —, by stannic chloride, 990  
 —, rate of polymerization of, 155  
 —, reaction with benzoquinone, 830  
 —, —, 2-pentene, 180  
 —, sulphur dioxide, 171  
 —, trimethylene, 190  
 —, triphenylmethyl, 834  
 —, relationship to rubber, 1087  
 —, resemblance to rubber, 1101  
 —, rubber-like material from, 173, 174, 175, 176, 177, 178, 179, 180, 183, 184, 1247  
 —, sodium-polymerized, cyclic structure of, 175  
 —, —, resemblance to natural rubber, 175  
 —, sodium rubber from, 1089  
 —, structure of, 1087  
 —, synthesis of, 178  
 —, thermal reactions of, 51  
 —, see also butadiene homologues  
 Isoprene-butadiene mixture, vulcanizing polymer of, 195  
 Isoprene dibromide, reaction with calcium polysulphide, 1171  
 —, rubber-like substances from, 1171  
 Isoprene emulsions, tanning, 1247  
 Isoprene-2-pentene reaction, aluminum chloride catalyst in, 190  
 —, effect of reactant ratio on properties of product, 190  
 —, properties of products formed in, 190  
 Isoprene polymer, curing of, 175  
 —, increasing rubber-like properties of, 200  
 —, production of light-colored, 181  
 —, rubber-like material from, 200  
 —, vulcanization of, 175, 183, 196  
 Isoprene polymerization, alkali-metal catalyst in, 178, 179  
 —, apparatus for, 179  
 —, arresting, 180  
 —, aryl diazonium fluoroborate catalyst in, 176  
 —, benzene-soluble product of, 180

- Isoprene polymerisation, catalysts for, 175, 176, 180  
 —, effect of catalyst on yield, 180  
 —, —, hydrogen ion concentration, 178  
 —, glacial acetic acid catalyst in, 175  
 —, homogenization of emulsion before, 179  
 —, hydrochloric acid catalyst in, 174  
 —, hydrogen-ion concentration in, 179  
 —, in aqueous emulsion, 178, 179, 180  
 —, in commerce, 176, 177  
 —, oxidizing substances as catalysts in, 180  
 —, oxygen catalyst in, 175, 179, 180  
 —, place of autoxidation in, 176  
 —, removal of oxidizing catalyst after, 180, 181  
 —, removal of product after, 179  
 —, sodium catalyst in, 175, 181, 182, 183  
 —, temperature control in, 179  
 —, use of acids in, 178  
 —, —, acrylic acid derivatives, 181  
 —, —, amyl ether in, 180

 —, —, caustic alkali in, 178  
 —, —, chlorinated compounds in, 180  
 —, —, emulsifiers in, 178  
 —, —, heat in, 179, 180  
 —, —, pressure in, 176  
 —, —, vegetable oils in, 180  
 —, velocity of, 184  
 —, x-ray studies of, 50  
 —, see also butadiene homologues, polymerization of
- Isoprene sulphone, action of alkali on, 172  
 —, effect of light on, 172  
 —, polymeric, allene linkage present in, 172  
 —, preparation, 171, 178  
 —, reaction with bromine, 171  
 —, —, potassium, 172
- Isoprene sulphone B, formation of, 172  
 —, melting point of, 172
- Isoprene sulphone dibromide, preparation of, 171  
 —, reaction with alcoholic sodium hydroxide, 171
- Isoprene tetrabromide, dibromoisoprene from, 170
- Isoprene-toluene condensation, sodium catalyst in, 194
- Isoprene units, in rubber, arrangement, 174, 1090
- Isopropenyl methyl ketone, isomerization, 551  
 —, polymerization, 550  
 —, —, by irradiation, 551  
 —, reaction with, stannic chloride, 551
- Isopropyl alcohol, influence on viscosity of nitro-cellulose lacquers, 966
- Isopropylamine, catalyst for cresol condensation, 347  
 —, condensation with acetaldehyde, 705  
 —, —, benzaldehyde, 705  
 —, —, formaldehyde, 705
- Isopropylbenzene, condensation with ethylene dihalides, 266  
 —, —, isoprene, 193  
 —, polymerisation with stannic chloride, 258  
 —, styrene homologues from, 254
- Isopropyl benzyl chloride, reaction with phenols, 1133
- Isopropylbenzyl chloride-rosin condensation, 1132
- Isopropylbenzyl chloride, rosin esters with, 799
- Isopropyl chlorosuccinate, 589
- Isopropyl esters of phenylacrylic acid, polymerization, 1083
- Isopropyl-naphthalene, as toxic constituent of coating, 154
- Isopropyl-naphthalenesulphonic acid, modifier, phenol-aldehyde resins, 419  
 —, reaction with formaldehyde, 419
- Isopropyl-xanthogenate tetrasulphide, rubber accelerator, 1172
- Isoquinoline derivatives, resins from, 739
- Isoafrule, coupling with diazotised p-nitroaniline, 734  
 —, effect of sunlight on, 261  
 —, ozonides of decomposition, 261  
 —, polymerisation, stannic chloride catalyst, 261  
 —, resins from, 261, 263
- Isosuccinic acid, reaction with resorcinol, 1245
- Isosuccinic acid-resorcinol resin, effect of lead, 1255  
 —, solvents for, 1255
- Isotiohydantoin, from thiocarbanilide, 575
- Isourea, condensation with malonic ester, 571  
 —, derivatives of, 571  
 —, reactions of, 571
- Isovaleric aldehyde, resinification of, 509
- Isovaleryl cyanamide, polymerisation of, 731
- Itaconic acid, dialkyl esters of, polymerization, 1085  
 —, esters, resinous polymers of, 1085, 1086  
 —, polymerisation of, 1085, 1086  
 —, polymerized modifier, for urea resin, 632
- Itaconic acid esters, polymers of, uses, 1086  
 —, rate of polymerization, 1085
- Itaconic acid polymers, as modifiers, 1086  
 —, use in phonograph records, 1086  
 —, with vinyl compounds, dispersing media from, 1086
- Itaconic acid resins, use of phthalide with, 942
- Itaconic anhydride, reaction with cyclopentadiene, 835, 836
- Ivory, natural, modifier, phenol-formaldehyde resins, 418
- Ivory-like castings, 589
- Ivory-like material, modified phenol-aldehyde resin, 437  
 —, urea-phenol-aldehyde resin, 674
- Ivory-like substance, from sulphur and casein, 1166
- Ivory scrap, filler, for molding composition, 463
- Ivory substitutes, from casein-furfural resins, 538
- Izod test with laminated materials, 1342

## J

- Japan, baked, in molded lubricants, 1327, 1328
- Japanese acid clay, catalyst, rubber-chlorination, 1110
- Japanese lac, modifier, for phenol-aldehyde resin, 398, 399  
 —, properties of varnishes from, 25  
 —, source of, 25
- Japanese lacquer, action on skin, 1205  
 —, source of, 1205  
 —, sulphurized, uses for, 1206  
 —, —, reaction with aldehydes, 1206
- Japanese sardine oil, fatty acids, polymerization, 1229
- Japan lac, constitution of, 516
- Japans, use of nitrocellulose-Teglac compositions as, 913
- Japan wax, in stencil sheets, 902
- Jar caps, from urea resins, 627
- Jars from vinyl resins, 1269
- Jayne, H. W., use of by-product coke ovens by, 360
- Jellies, theory of formation, 30, 31  
 —, from cellulose, 66
- Jelly, from silk, 69
- Jig-boring, of molds, 1201
- Juniper oil, resin from, 1253
- Jute, fiber structure of, 64

## K

- Kaolin, catalyst, 1131  
 —, use in alkyl resins, 949  
 —, —, synthetic rubber, 196, 197  
 —, with phenol and urea resins, 624
- Karaya gum, retarder, urea and formaldehyde resins, 643  
 —, stabiliser, urea-formaldehyde resins, 597,
- Kashimoto-body, formulation of, 850
- Kauri-butanol tests, for solvent evaluation, 1369
- Kauri copal benzyl ester, preparation of, 810
- Kauri gum, distillation with turpentine, for varnish testing, 1367  
 —, substitute for, 1183  
 —, urea resin lacquers with, 632  
 —, use in alkyl resins, 914  
 —, with ester gum, 817  
 —, —, rubber, 1092

- Kauri reduction value, durability of varnishes, 1367, 1368**

 —, — wire, 965  
 —, formation, in Diesel engines, 210  
 —, from acetylene polymers, 153  
 —, — acid sludge, 217  
 —, — alkyl resin, 894, 897  
 —, — alkyl-urea-formaldehyde resin, 661, 662  
 —, — amine-aldehyde resins, 698, 697  
 —, — benzene-sulphonamide-aldehyde resin, 717, 718  
 —, — butadiene polymers, vulcanised, 185  
 —, — butadiene-stand oil co-polymer, 199  
 —, — butadienol esters, 182  
 —, — carbohydrate resins, 788  
 —, — coal tar resins, 276  
 —, — crotyl cellulose, 1081  
 —, — cumarone resin, 119, 123, 129, 183  
 —, — cymene, chlorinated, 1155

- Lacquer, from ester gum and nitrocellulose, 822
- , — ester gum, nitrocellulose and cumarone resin, 823
  - , — fat oil, 781
  - , — hydrogen and carbon monoxide, 1255
  - , — ketone-furfural resins, with nitrocellulose, 447
  - , — gas-purification extract, 122
  - , — glycerol diacetate, 822
  - , — glycerol-urea-acetaldehyde, 665
  - , — gutta-percha, chlorinated, 1128
  - , — leather base, 1255
  - , — lignite extractions, 275
  - , — natural resins, 18
  - , — naphthalene, 1137
  - , — naphthenic acids, 207
  - , — nitro resins, 728, 729
  - , — 1,3-diene polymers, 185
  - , — pectous material, 763
  - , — phenol-alcohol resins, 332
  - , — phenol-aldehyde resin, 400, 416, 1044
  - , — phenol-aldehyde-alkyd resins, 447
  - , — phenol-aldehyde-urea resins, 673, 676
  - , — phenol-benzoylbenzoic esters, 433
  - , — phenol-fatty acid esters, 1233
  - , — phenol-furfural-nitrocellulose compositions, 447
  - , — phenol-resins, alkylated, 411, 412
  - , — Plastopals and nitrocellulose, 634, 635
  - , — polyacrylic acid, 1079
  - , — polycyclopentadiene, 188
  - , — polystyrene, 241, 242, 246, 247, 248, 961
  - , — polyvinyl acetals, 1062, 1064, 1066
  - , — polyvinyl acetate, 1025
  - , — polyvinyl chloroacetate, 1025
  - , — polyvinyl esters, 1059
  - , — polyvinyl halides, 1039, 1043, 1044
  - , — resorcinol-isosuccinic acid resin, 1255
  - , — rubber, halogenated, 1105, 1108, 1109, 1110, 1111, 1115, 1116
  - , — rubber, oxidized, 1093, 1095, 1098
  - , — rubber, synthetic, 189
  - , — sulphamide-aldehyde resin, 713, 714, 717, 718
  - , — tar acid-aldehyde resins, 361, 362
  - , — thiourea resins, 654
  - , — titanium glycolate, 1239
  - , — turpentine-formaldehyde condensation, 782
  - , — urea resin, 565, 631, 635, 636, 646, 669, 678
  - , — vinylacetylene, 150
  - , — vinyllethynyl carbinols, 151
  - , — vinyl resins, 249, 1023, 1027, 1031, 1033, 1047, 1065, 1067
  - , — waste distillates, 320
  - , — xylenesulphonamide-aldehyde resin, 717, 718
  - , — glossy brushing, use of Teglaes in, 912
  - , — ratio of ester gum to solvent in, 822
  - , — resins, nature of, 821, 822, 827
  - , — rough surface from, 961
  - , — shock-resistant, 1248
  - , — stoving, sulphur containing, 1204
- Lacquer compositions containing no nitrocellulose, 914
- Lacquer films, effect of reagents on, 822, 826, 827
- Lacquer industry, expansion of, 10
- Lacquer plasticisers, use of alkyd resins as, 874
- , — glycol monoether carbonates in, 870
- Lacquer substitutes, from fatty oil acids, 803
- Lacquering of light bulbs, 940
- Lacs, as a mesomorphic state, 62
- , — hardening by formaldehyde, 516
  - , — preparation with ricinoleic acid distillation residue, 1224
- Lactams, preparation and properties of, 999
- Lactic acid, in alkyd resins, 906, 936
- , — chlororubber paints, 1121
  - , — hydrocarbon-aldehyde resin, 265
  - , — phenol-aldehyde condensation, 310, 349, 354, 423, 433, 439
  - , — resin formation, 274
  - , — resin purification, 336
  - , — urea-formaldehyde condensation, 610, 673, 675, 685
  - , — vinyl resins, 1029, 1032, 1033, 1059
- Lactic acid, preparation and properties of, 1003, 1004, 1070
- , — reaction with formaldehyde, 1004
  - , — glycerol, 1004
  - , — shellac-like resin from, 1006
  - , — use of, 463
- Lactic acid resin, preparation of, 1003, 1004
- Lactic anhydride, properties of, 1003, 1004
- Lactio esters, fluxing agents, 337
- Lactides, preparation and properties of, 1003, 1001, 1003, 1004, 1005, 1007
- Lactone formation in shellac, 1006
- Lactones, preparation and properties of, 1070, 1031, 1002, 1003, 1073
- Lactose in urea-formaldehyde condensation, 616
- Lakes, dye, from amine-aldehyde resins, 701
- , — from urea resins and acid dyes, 642, 648
  - , — from cumarone resins, 118
  - , — metallic soaps in, 790
  - , — phenol-sulphur resins in, 1187
  - , — polyethylene oxide in, 993
- Lamellar structures, nature of, 32
- Laminated board, properties of, 9, 338, 362, 1282
- Laminated duck, uses of, 474
- Laminated glass, alkyd resins in, 887, 963, 989
- , — furfural-p-toluenesulphonamide, 535
  - , — lactic acid resin in, 1004
  - , — phenolic resin in, 480
  - , — polyacrylic esters in, 1077
  - , — polystyrene in, 251, 252
- Laminated insulators, 1247
- Laminated material, coefficient of friction in, 1351
- , — cold flow test on, 1353, 1354
  - , — compressive strength of, 1342
  - , — dielectric test for, 1345, 1346, 1348
  - , — distortion under heat, 1354
  - , — effect of exposure, 1350
  - , — hardness tests for, 1351
  - , — multi-colored casting, 1312, 1314
  - , — strength of, 1280, 1342
  - , — test for power factor, 1348, 1349
  - , — tentative standards for, 1340
  - , — thermal conductivity of, 1354
  - , — volatile material in, 1344
- Laminated paper, 472, 473, 643, 829
- Laminated products, containing rubber, 1099
- , — decoration of, 483, 484
  - , — formation of, 938, 987, 1280, 1281
- Laminated products, from alkyd resins, 949
- , — phenol-aldehyde resins, 452, 470, 471, 472, 473, 474, 475, 476, 477, 478, 479, 480, 481
  - , — urea-formaldehyde resin, 604, 623, 625, 627
  - , — xylene-formaldehyde resin, 370
  - , — vinylite resins, 1045
- Laminated sheet, flexural strength of, 1341
- Laminated sheets, from amine-aldehyde resins, 694
- , — cellulose esters, 963
  - , — lactic acid resin, 1004
  - , — mica, 474, 475
  - , — phenolic resin, 478, 485, 673
- Laminated sound records, manufacture, 1337, 1338, 1339
- Laminated stock, bonding strength of, 1352, 1353
- Laminated tubes, from amine-aldehyde resins, 694
- Laminated wood, preparation of, 963
- Lampblack, filler, 193, 483, 719
- , — in acrylic acid derivatives, 1076
  - , — alkyd resin, 981
  - , — phenol-aldehyde resin, 287, 318
  - , — polyvinyl lacquers, 1026
  - , — rubber, synthetic, 195, 196, 197, 198
  - , — urea resin, 643
  - , — waterproofing compositions, 1158
- Lanolin in furfural-phenol resin, 531
- , — furfural-urea resin, 670
  - , — lubricant, 435
- Lanolin substitute, from oleic acid, 1212
- Lard oil, chlorinated, as film strengthener, 1158
- Latent catalysts in urea-formaldehyde resin, 617, 618
- Latex, action of acids on, 1091, 1100, 1113
- , — chlorine on, 1125
  - , — heat on, 1091
  - , — hydrogen peroxide on, 1094

- Latex, adhesive from, 1092, 1094  
 —, artificial, from diene polymers, 152, 179  
 —, —, methyl acrylate polymers, 1076  
 —, —, polystyrene, 234, 245  
 —, as electrical insulator, 1103  
 —, —, impregnant, 1246  
 —, —, molding composition, 1103  
 —, —, paper size, 1094  
 —, —, softening agent in urea resins, 595  
 —, coagulation, 1091, 1106  
 —, constitution of, 1090  
 —, in artificial gutta-percha, 790  
 —, —, chloronaphthalene composition, 1153  
 —, —, chloroprene rubber latex, 157  
 —, oxidation of, 1094  
 —, precipitation of, 1092  
 —, preservatives for, 647, 1091  
 —, putrefaction of, 1091  
 —, solvent, phenol-aldehyde condensate, 435  
 —, source of, 1090  
 —, sponge rubber from, 1334  
 —, stability of, 1091  
 —, vulcanization of, 1092  
 Latex-phenol-formaldehyde product, preparation and properties of, 1103  
 Lathes, use, finishing moldings, 1330, 1331  
 Lauric acid, use in alkylid resins, 907  
 Lauryl alcohol, reaction with phthalic anhydride, 903  
 Lauryl chloride, use with cellulose, 1222  
 Lavender oil, resin from, 1253  
 Lead, action on cashew-shell oil, 1230  
 —, —, resorcinol-isosuccinic acid resin, 1255  
 —, catalyst, condensation, 355, 800  
 —, —, oxidation, 210, 271  
 —, —, polymerization, 521  
 —, filler, for phenol-aldehyde resin, 459  
 —, in moldings, 434, 1294  
 Lead acetate, action on phthalic anhydride, 957  
 —, buffering agent, urea-formaldehyde condensation, 612  
 —, catalyst, acrolein polymerization, 502  
 —, —, formaldehyde condensation, 512  
 —, —, furfural polymerization, 521  
 —, —, phenol-formaldehyde reaction, 357, 369  
 —, —, rosin esterification, 795  
 —, in liming of rosin, 772  
 —, precipitant, sweet-almond-oil resin, 1253  
 Lead carbonate, catalyst, condensation, urea and formaldehyde, 591  
 Lead chromate, alkylid resin primer coatings, 976  
 —, resin purification with, 336  
 Lead driers, uses of, 126, 796, 1223  
 Lead hydroxide, catalyst, acrolein polymerization, 502  
 —, catalyst, aldol formation, 499  
 —, oxidation  $\alpha$ -bromopropionaldehyde dimethyl acetal, 1070  
 Lead linoleate, drier, use of, 401, 1216  
 Lead molds, for phenolic resin casting, 468  
 Lead monoalkylphthalic acid preparation of, 950  
 Lead naphthenates, 206, 207  
 Lead oleate in alkylid resins, 881  
 —, rubber, 1103  
 Lead oxide, action on cresol, 271, 273  
 —, crude tar oil, 273  
 —,  $\alpha$ -naphthol, 273  
 —, phenol, 270, 273  
 —, catalyst, cashew-shell oil, 1231  
 —, —, ethylene oxide, 991  
 —, —, formaldehyde condensation, 512  
 —, —, glycerol and acids, 209  
 —, —, 1,3-diene polymerization, 180  
 —, —, vinyl bromide, 1087  
 —, dehydrogenating agent, 216  
 —, use in alkylid resins, 911, 921, 922  
 —, —, hardening rosin, 772  
 —, —, phenol-formaldehyde reaction, 281, 343, 408, 450  
 Lead peroxide, polymerization of isoeugenol, 262  
 Lead phenolate, uses of, 273, 438  
 Lead resinate, use of, 1251  
 Lead salts, action on pine tar, 781  
 —, —, phenol-aldehyde resin, 354  
 —, neutralizing agents, 344  
 Lead soaps, in lubricants, 790  
 —, —, phenol-aldehyde resin, 438  
 Lead sec-amybenzoyl-o-benzoic acid salt, preparation of, 953  
 Lead sulphate, uses of, 434, 964  
 Lead sulphonate, drier, 219  
 Lead tetraethyl, catalyst, vinyl resins, 1025, 1040  
 —, catalyst, polymerization, styrene, 242  
 Lead tetrafluoride, as fluorinating agent, 1156  
 Leaded zinc oxides in Rexyl vehicles, 977  
 Leaking properties of metallic joints, improvement, 979  
 Leather, artificial, from butadiene homologue polymers, 198  
 —, —, —, chlororubber, 1128  
 —, —, —, naphthenates, 207  
 —, —, —, tar oil hydrocarbon-acetone resin, 275  
 —, —, —, vinyl resins, 1030  
 —, as xerogel, 37  
 —, coating of, 453, 788, 911, 967, 1207, 1209  
 —, filler, 1275  
 —, imitation, amine-aldehyde resins, 692  
 —, impregnation by alkylid resins, 924  
 —, —, chloroprene, 159  
 —, —, phenol resin, 475  
 —, —, rubber, 647  
 —, —, urea resins, 647  
 —, lacquer base from, 1255  
 —, waterproofing of, 130, 139, 1208, 1248  
 Leather dressings from nitro resins, 729  
 —, —, Rezyls and nitrocellulose, 967  
 —, —, sulphurized fatty acid salts, 1210  
 Leather finishing, alkylid resin in, 978  
 —, salicylic acid-formaldehyde resin in, 374  
 "Leather gum," urea resin coatings with, 633  
 Leather linings, use of, in polymerization apparatus, 179  
 Leather plasticizer, polyalkylene oxide as, 993  
 Leather preservative, 1-chloronaphthalene-formaldehyde resin as, 266  
 Leather scrap, modifier, phenol-aldehyde resins, 418  
 Leather substitute, fillers for, 485, 486  
 —, from phenol resin, 485, 486  
 —, —, polyacrylic acid derivatives, 1078  
 —, —, vinyl resins, 1052  
 Leather tanning, cumarone resin in, 140  
 —, cumarone sulphonated resin in, 121  
 —, phenol-aldehyde sulphonated resins in, 418, 419, 420, 421  
 Leather-like material from halogenated rubber, 1105, 1108  
 Leaves, impregnation method, 1245  
 —, use, decoration of moldings, 1333  
 Lemon oil, cymene from, 1253  
 Lenses, from polystyrene, 252  
 —, urea-formaldehyde resins, 598  
 Lepidine, from acetaldehyde and aniline, 703  
 —, from acetylene and aniline, 703  
 Leuco bases, action on resins, 331, 335  
 Levulinic aldehyde, formation of, 1087, 1089  
 Levulinic acid, 421, 542, 1080, 1093  
 Levulose, in carbohydrate resins, 761  
 —, in urea-formaldehyde resins, 616  
 Lichenin, horn substitutes from, 750  
 Liebermann-Storch test, 1259  
 Life test on gear stock, 1352  
 Lifting of coatings, nature of, 960  
 Light, discoloration by, 331  
 —, effect on acetylene, 144  
 —, —, amine-aldehyde resin, 663  
 —, —, butadiene derivatives, 171  
 —, —, chloroprene, 157  
 —, —, chlororubber films, 1119, 1120, 1121  
 —, —, cumamylidenecacetylene, 563  
 —, —, cracked distillates, 230  
 —, —, cyclopentadiene, 156  
 —, —, dibenzylidene-stannic chloride complex, 563  
 —, —, ethyl itaconate, 1085  
 —, —, gum formation, 222, 223, 224, 225, 230  
 —, —, isoprene, 174  
 —, —, isoprene sulphone, 172  
 —, —, methyl acrylate, 1070, 1071, 1072, 1081  
 —, —, methyl ketopentadienecarboxylate, 563  
 —, —, phenol-aldehyde condensate, 387, 324, 335  
 —, —, rubber chlorination, 1106, 1108

- Light, effect on rubber iodination, 1114
  - , — styrene, 238, 239, 240, 241
  - , — vinyl acetate, 1084
  - , — vinyl ester-aldehyde reaction, 1064
  - , — vinyl ethinyl carbinols, 151
- Light-absorption, — measurements of, polystyrene structure, 232, 233
- Light bulbs, lacquering of, 940
- Light-colored compositions, molding temperature, 1319, 1320
- Light filters, from vinyl resins, 1052
- Light oils, in rosin distillation, 779
  - , — phenol-aldehyde resins, 307, 362
- Light-resistance, of hydroxybenzoic-acid resins, 378
  - , of glycerol phthalate, 958
- Light-sensitive amine-aldehyde products, 699
  - coatings, 141, 1251
  - furfural products, 535, 538, 539
- Light-stability, of cellulose esters, 21, 719, 720

- Linoleum-like plastics, from acid sludge, linseed oil, 1234
- Linoleum manufacture, 775, 777, 821
- Linoleum printing, use of alkylid resin in, 922
- Linoleum substitute, synthetic resin composition, 1246
  - , vinyl resins, 1030
- Linoxyn, uses of, 199, 825, 1210, 1212, 1234
- Linseed diglyceride, preparation of, 951
- Linseed diglyceride half-acid phthalate, preparation of, 951
- Linseed oil, absence of webbing in, nature of, 40
  - , bleaching of, 929
  - , blown, action of sulphur chloride on, 1207
  - , —, catalyst for polyfurfurylene, 243
  - , —, with castor oil, 1227
  - , bodied in alkylid resins, 927
  - , color-retention of, 975
  - , emulsified, vulcanization of, 1210
  - , enzymatic hydrolysis of, 930
  - , gelatinization of, 1226
  - , in alkylid resins, 928-931
  - , in alkylid resins, modified, 935, 936, 973
  - , brake material, 1204
  - , cold-molding composition, 1286
  - , core oil, 821
  - , cumarone resin, 131, 137
  - , electrical insulation material, 986
  - , ester gum, 825
  - , furfural-acetone resin, 537
  - , lined rosin, 772
  - , phenol resin, 485
  - , tar-oil resin paints, 122
  - , tricresyl phosphate resins, 1240
  - , urea resins, 636, 669
  - , waterproof sandpaper, 1248
- inhibitor, for gelatinisation of tung oil, 1216
- manganated, in japan, 1204
- oxidation of, 1225, 1226
- oxidized, in chlororubber, 1124
- , reaction with sulphur chloride, 1208
- polymerisation of, 818, 1219
- protective colloids in, 36
- reaction of, at high temperature, 860
- reaction with aromatic diamines, 1219
- , — chlorine, 1231, 1235
- , — chromyl chloride, 1229
- , — copals, 809
- , — ferric chloride, 1218
- , — glycol, 994

- Linseed oil, reaction with mineral oil acid sludge, 1234  
 —, — resorcinol, 1233, 1234  
 —, — silicon tetrachloride, 1229  
 —, — sodium bisulphite, lead-manganese naphthenate, 1228  
 —, — sulphur 1207, 1211  
 —, — sulphur monochloride, 1208  
 —, — titanium tetrachloride, 1229  
 —, — zinc oxide, 1227, 1228  
 —, — softening agent, urea resins, 595  
 —, — solubility of Aroclors in, 1146  
 —, — solvent for, cumarone resins, 117, 119  
 —, —, natural resin esters, 400  
 —, —, phenol-aldehyde resin, 397  
 —, —, polyvinyl alcohol, 1056  
 —, —, resin from cracked gasoline, 192  
 —, —, sulphonated, uses, 1234  
 —, —, sulphurized, 1207, 1208, 1209  
 —, —, Tekaol from, 1227  
 —, —, uses, 464, 1228  
 —, —, vulcanized in brake lining, 1209  
 —, —, chlororubber, 1124  
 —, —, with horn scrap, uses of, 1234  
 —, —, metallic resinates, resin glycerides from, 803  
 —, —, semi-drying oil from gilsonite 274  
 Linseed oil acids, chlorination of, 1138  
 —, —, distilled, in alkyl resins, 922, 923  
 —, —, esterified with sorbitol, 815  
 —, —, in alkyl resins, 875, 918, 919, 921-925, 927, 930-932, 935, 936, 984  
 —, —, —, furylethylene polymerization, 522  
 —, —, —, urea-formaldehyde lacquers, 662  
 Linseed oil acid salts, reaction with dimethylolurea-ethylene chlorhydrin, 667, 668  
 Linseed oil films, nature of, 153  
 Linseed oil paints, 959, 975  
 Linseed oil-soluble resins, 1131, 1136  
 Linseed oil stand oil, 199, 1216, 1226  
 Linseed oil-stearin pitch insulating compound, 1203  
 Linseed oil substitute, from balata or gutta-percha, 1092  
 —, —, rosin, 778  
 —, —, vinylacrylic acid polymers, 1084  
 —, —, vinyl resin, 1044  
 Lipase, use of in hydrolysis of fatty oils, 930  
 Liquid ammonia, in Wurtz-Fittig reaction, 1141  
 Liquid crystals, formation of, 44  
 —, —, nature of stability of, 44  
 —, —, x-ray patterns of, 44  
 Liquid crystals and resins, relationship between, 45  
 Liquid-phase gum, in manufactured gas, 257  
 Liquid-phase oxidation, of ethyl alcohol, 496  
 Liquids, plasticity of, 31  
 —, —, x-ray pattern of, 79  
 Liquids and solids, nature of, 27, 31  
 Liquors, from woodpulp, 752, 753  
 Litharge, action on phenols, 273  
 —, —, filler, 485, 1126  
 —, —, in purification of coal-tar naphtha, 115  
 —, —, in reaction of alkyl resins, 964  
 —, —, fatty acids, 815, 1238  
 —, —, nitrobenzene and o, o'-dithioaniline, 1198  
 —, —, oil diglycerides, 951  
 —, —, neutralizing agent, 815  
 Lithium alkyls, catalysts, 182  
 Lithium amide, reaction with vinylacetylene, 151  
 Lithium resinate, catalysts, 794  
 Lithographic plates, use of resins in, 140, 539, 1251  
 Lithol Red (B), preparation of, 948  
 Lithopone, in alkyl resins, 922, 978, 984  
 —, —, linoleum, 198  
 —, —, phenol-aldehyde resins, 431  
 —, —, rubber, chlorinated, 1120  
 —, —, rubber, synthetic, 196  
 —, —, urea resin molding, 617  
 Livering of rosin varnish, 771  
 Loading coils, cores for, 1249  
 Long molecules, action of heat on specific viscosity, 78  
 Long molecules and gel formation, correlation of, 76  
 Long-oil varnish, cumarone resin in, 125, 126, 127  
 —, —, nature of, 801  
 Loss factor in insulation, 1348  
 Loudspeaker diaphragms, from urea resins, 624  
 Low molecular weight compound, viscosity of, 72  
 Low temperature coal tar, resins from, 273, 275  
 Lower oxides of carbon, formation of, 1013  
 Lubricant from benzol, crude, polymerised, 120  
 —, —, cumarone-resin, 112  
 —, —, glycerol, 504  
 —, —, halogenated hydrocarbons, 1154  
 —, —, sulphonic acids, 219  
 —, —, tall oil, 755  
 —, —, ground-joint, alkyl resin, 891  
 —, —, metallic soaps in, 790  
 —, —, mold, 455, 463, 620, 621, 1276  
 —, —, molding, 1326, 1327, 1328  
 Lubricating greases, uses of, 249  
 Lubricating oils, as a mesomorphic state, 62  
 —, —, action on chloroprene rubber, 159  
 —, —, rubber hydrochloride, 1112  
 —, —, addition of polymerized hydrocarbons, 227  
 —, —, chlorinated compounds in, 1140  
 —, —, deblooming of, 230  
 —, —, from olefin polymers, 166, 185, 194  
 —, —, halogenated paraffin, 1158  
 —, —, tar oil hydrocarbons, 275  
 —, —, improvement in film strength, 1158  
 —, —, in sulphur-resin mastic, 1164  
 —, —, refining of, 227  
 —, —, resins from, 202, 203  
 —, —, use of cumarone resin in, 140  
 —, —, polyindene in, 200  
 —, —, polystyrene in, 200, 249  
 —, —, rubber in, 200, 1097  
 —, —, vinyl resins in, 1011, 1031  
 Luminescent paints, preparation of, 247, 248, 450, 1125  
 Luster, test for, 1356  
 —, —, improvement of, 669  
 Luting, resins in, 360, 1313  
 Lyophilic properties of urea-formaldehyde condensation, 62

## M

- Machining, of alkyl resins, 873  
 —, —, of molded products, 1270  
 —, —, of inserts, 1331  
 Macro-crystals, formation of, 30, 31  
 Macrocyclic ketones, odor of, 998  
 Macropolymerization, nature of, 42, 48  
 Magnesium acetate, catalyst, formaldehyde condensation, 512  
 Magnesium, action on benzaldehyde, 508  
 —, —, benzyl chloride, 1131  
 —, —, furfural, 521  
 —, —, rosin, 772, 800  
 —, —, rubber, 1092  
 —, —, styryl dibromide, 253  
 Magnesium alkylbromides, 783  
 Magnesium alloys, coating with phenol resin, 449  
 Magnesium carbonate, basic, addition to formalin, 613  
 —, —, in floor covering, 983  
 —, —, in phenol-aldehyde condensation, 436-438  
 —, —, in rosin compositions, 777  
 —, —, in synthetic rubber, 196  
 —, —, in urea-formaldehyde condensation, 591, 612  
 Magnesium chloride, as ansovo-acid, 194  
 —, —, hydrolysis of, 356  
 —, —, in 1,3-diene polymerisation, 182  
 —, —, in diolefin-monoolefin co-polymerization, 192  
 —, —, in phenolic resin coating, 448, 449  
 —, —, in urea-formaldehyde condensation, 612  
 Magnesium hydroxide, dispersing agent for rubber, 1173  
 —, —, in formaldehyde condensation, 512  
 —, —, in magnetic cores, 1249  
 —, —, in phenol-aldehyde resins, 438  
 —, —, resin precipitation by, 695  
 —, —, resin purification with, 337  
 Magnesium methoxide in furfural-acetaldehyde condensation, 519  
 Magnesium oleate, in emulsification of 1,3-dienes, 180  
 —, —, in factrice oil paint, 1206

- Magnesium oxide, in aldol polymerisation, 499  
 —, in alkyd resins, 908, 981  
 —, in ethylene oxide polymerisation, 991  
 —, in glycerol polymerisation, 995  
 —, in linoleum, 198  
 —, in phenol-aldehyde condensation, 324, 370, 436-438  
 —, in refractory filler, 1250  
 —, in rosin, 792, 794  
 —, in styrene separation, 254  
 —, in synthetic rubber, 196, 198  
 Magnesium silicate, hydrated, as catalyst, 1131  
 Magnesium stearate as mold lubricant, 620  
 Magnesium sulphate, in hydrocarbon-aldehyde condensation, 265  
 —, in urea resin, 647  
 Magnesylinole, reactions of, 743  
 Magnethylmethylketole, reactions of, 743  
 Magnethylpyrrole, condensations of, 742  
 Magnetic cores, preparation of, 135, 1249  
 Mahogany acids, from acid sludge, 218  
 Maintenance of molds, 1804  
 Maise oil, in phenol-aldehyde resins, 424  
 Malachite green, use of, 458  
 Maleic acid, from furfural, 888  
 —, in alkyd resins, 876, 888, 901, 925, 932, 935, 949  
 —, in condensations, 888, 901, 910  
 —, in phenol-aldehyde resins, 810, 854, 439  
 —, reaction with carvacrol, 1254  
 —, — castor oil, 855, 909, 1028  
 —, — chloroprene, 160  
 —, — 2-phenyl-1,3-butadiene, 160  
 Maleic acid esters, polymerisation of, 1076  
 Maleic anhydride, action on cracked distillates, 224  
 —, elucidation of structures of, by, 830  
 —, in methylene ketone, 550  
 —, in rosin-modified alkyds, 857  
 —, in rosin-modified phenol-formaldehyde resins, 857  
 —, in vinyl resins, 1034, 1044  
 —, in urea and formaldehyde, 610  
 —, purification of benzene with, 836  
 —, quinoidal nature in, 831  
 —, reaction with abietic acid, 845  
 —, — amylene, 854, 855  
 —, — anthracene, 839  
 —, — aromatic hydrocarbons, 839  
 —, — benzalazine, 854  
 —, — butadiene, 822  
 —, — 1,3-butylene glycol, 855, 898, 909, 1029  
 —, — chloroprene, 155, 160  
 —, — cineole, 846  
 —, —  $\beta$ -coupein, 861  
 —, — cyclohexadiene, 837  
 —, — cis-cyclohexadiene- $\Delta^5$ -1,2-dicarboxylic anhydride, 837  
 —, — cyclopentadiene, 835  
 —, — dehydration product of linalool, 843  
 —, — dextrose, 761  
 —, — 1,2,5,6-dibenzanthracene, 841  
 —, — 2,3-10,11-dibenzoperylene, 841  
 —, — 2,5-dimethyl furan, 847  
 —, — 1,2-dimethylindole, 849  
 —, — dipentene, 845  
 —, — 1,10-diphenyl-1,3,5,7,9-decapentaene, 854  
 —, — asym-diphenylethylene, 854, 855  
 —, — sym-diphenylethylene, 168  
 —, — 1,3-diphenyl-1,3,5,7-octatetraene, 854  
 —, — divinylacetylene, homologues, 160, 161  
 —, —  $\alpha$ -eleostearic acid, 855  
 —, —  $\beta$ -eleostearic acid, 855  
 —, — ester gum, 857  
 —, — ethylbenzene, 839  
 —, — furan, 846  
 —, — 1,3,5-hexatriene, 853, 854  
 —, — hydrazine hydrate, 786  
 —, — isomerised  $\alpha$ -pinene, 844  
 —, — isopropyl alcohol, 890  
 —, — indene, 895  
 —, — methyl abietate, 856  
 —, — methyl coumalate, 847  
 —, — 2-methyl furan, 847  
 —, — 3-methyl furan, 847  
 —, — 2-methylindole, 849  
 Maleic anhydride, reaction with 2-methyl pyrrole, 847  
 —, — myrcene, 843  
 —, — oiticica oil component, 861  
 —, — olefins, 168  
 —, — perylene, 841  
 —, —  $\alpha$ -pinene, 845  
 —, —  $\beta$ -pinene, 845  
 —, — 2-phenyl-1,3-butadiene, 160  
 —, — polyenes, 853, 854, 855  
 —, — pyrrole, 847  
 —, — rosin, 765, 804  
 —, — stilbene, 280, 854  
 —, — styrene, 168, 244, 854, 884, 895  
 —, — terpinene, 783, 844  
 —, — terpinolene, 845  
 —, — tetraphenylcyclopentadienone, 842  
 —, — toluene, 839  
 —, — tung oil isomers, 1216  
 —, — vinyl resins, 884, 895, 1058, 1059  
 Maleic anhydride- $\alpha$ -terpinene reaction product, 844  
 Maleic anhydride- $\alpha$ -terpinene-abietic acid reaction product, 844  
 Malic acid, in alkyd resins, 876, 888, 888  
 —, — malomalic acid from, 888  
 Malonanilide, resin from, 733  
 Malonic acid, reactions of, 571, 909, 1012, 1013, 1015, 1198  
 —, — preparation and properties of, 1013  
 Malonyl chloride, preparation and properties of, 1012, 1014  
 Malt, phenolic resins from, 762  
 Mandelic acid, reactions of, 1003  
 Mandrel test, for flexibility of varnishes, 1870  
 Mandrel, use of, 475  
 Manganated linseed oil, in japan, 1204  
 Manganese acetate, in urea-formaldehyde condensation, 612  
 Manganese borate, catalyst, 180, 806  
 Manganese, catalyst, 209, 497, 1231  
 Manganese chromite, catalyst, 495  
 Manganese driers, 206, 210, 401, 785  
 Manganese monoalkyl phthalic acid, preparation of, 950  
 Manganese oxides, catalysts, 180, 211, 216, 270, 408, 549, 1132  
 —, — uses of, 336, 450, 460, 517, 567, 1276  
 Manganese resinate, catalysts, 755, 1102, 1230  
 Manganese salts, in pine-tar, 781  
 —, in rosin oxidation, 774  
 —, in vinyl polymerisation, 1038  
 Manganese soaps, uses of, 210, 401, 438  
 Manganese sulphate, catalyst, 122  
 Manila copal, in alkyd resins, 913  
 —, in phenol-aldehyde resins, 398, 486  
 —, in rubber, 1092  
 —, in sound records, 1336  
 —, — reaction with butanol, 810  
 —, — formaldehyde, 776  
 —, — glycerol, 807, 808  
 —, — hydroxy carboxylic acids, 810  
 —, — polyvinyl acetate, 1032  
 Mannitol, in alkyd resins, 864, 886, 890, 911, 936  
 —, in natural resins, 796, 810, 811  
 —, in phenol-aldehyde resins, 427, 429  
 Manufacture, of acetaldehyde, 496, 497  
 —, of large moldings, 1332, 1333  
 —, of light-colored articles, 1332  
 —, of urea, 566, 567, 568  
 Many-membered rings, nature of, 866  
 Marble, uses of, 251, 1125  
 Marble-effects, by injection, 1335  
 Marble-like resins, from potassium acid tartrate, 468  
 —, from sulphonamid-aldehyde reaction, 721  
 Marine glue, nature of, 1004  
 Marine paints, ester gum in, 820  
 Marine piling, treated with cymene resins, 1155  
 Mar resistance, tests for, 1377  
 Mastic, incorporation of, into alkyd resins, 943, 978  
 Mastic compositions, 137, 138, 1205  
 Mastication, of rubber, 1023, 1108, 1109  
 Masticator, uses of, 1279, 1280, 1316  
 Matchee, resins in, 824, 1244

 Methylamine, catalyst, acrolein polymerization, 502  
 —, cresol condensation, 347  
 —, phenylacetylene polymerization, 162  
 —, formation of, 309, 327, 379  
 —, reaction with carbon disulphide, 1197  
 —, formaldehyde and hydrogen sulphide, 1181  
 —, succinic aldehyde and acetoacetic esters, 560  
 Methylamine hydrochloride, condensing agent, acetophenone and formaldehyde, 557  
 5-Methyl-7-amino-indazol, reaction, with urea, 684  
 Methylaminophenols, catalysts, phenol-formaldehyde reaction, 340, 347  
 N-Methyl-p-aminophenols, formation of, 700  
 $\alpha$ -Methylaminopropiophenone, formation of, 557  
 Methylamine, condensation with formaldehyde, 699  
 o-Methylanisole, reaction with p-nitrobenzaldehyde, 383  
 Methylanthrones, reactions of, 556, 557  
 Methylated xylan, 763  
 Methylation, of chitin, 1255  
 —, of 4,4'-dihydroxydiphenyldihydro rubber, 1114  
 —, of isoeugenol, 262  
 N-Methyl-N-benzimidazolium iodide, resinification of, 737  
 Methyl benzoate, in phenol-aldehyde resins, 431  
 Methylbenzyl chloride, rosin esters with, 799  
 1-Methylbutadiene, polymerization of, 169  
 2-Methylbutadiene, *see* Isoprene  
 2-Methyl-2,3-butadiene sulphone, reaction of, 171, 172  
 2-Methyl-1-butene, from hydrorubber, 1096  
 2-Methyl-1,3-butylene glycol, synthesis of, 178  
 1-( $\alpha$ -Methyl- $\alpha$ -carboxy)-indolizine-2,3-dicarboxylic acid, reduction of, to resin, 852  
 Methyl cellulose, uses of, 446, 655, 834, 954, 1244  
 Methylchavicol, polymerization of, 260, 261, 262  
 Methyl chloride, in polystyrene, 237  
 2-Methyl-3-chlorobutadiene, in polymerization of 1,3-dienes, 181  
 Methyl cinnamate, polymerization of, 1082, 1083  
 Methylcinnamylvinyl ketone, condensation with isatin, 744  
 Methyl cinnamylidenemalonate, gums from, 725  
 Methyl coumalate and maleic anhydride, reaction of, 847  
 $\beta$ -Methylcrotonic acid phenyl esters, polymerization of, 1082  
 Methylcumarone, preparation and properties of, 96  
 1-Methyl-1,3-cyclohexadiene, polymerization of, 189  
 Methylcyclohexanol, in alkyd resins, 916, 936  
 Methylcyclohexanone, reaction with phenol-aldehydes, 390  
 —, polyvinyl alcohol, 1063  
 —, pyrrole, 741  
 —, sorbitol, 558  
 2-Methylcyclohexanone, reaction with sugar and alcohol, 761  
 Methylcyclohexyl adipate, softening agent, urea resins, 849  
 Methylcyclopentane, chlorination of, 220  
 4-Methyl-3,5-dicarbethoxy-3 (1-ethylol)-2,6-heptandione, formation of, 546  
 Methyl-dihydroxyamyl ketone condensation of, 542

- Methyl-1,8-dimethyl-1,8-dihydropyriminazole-4,5-, 6,7-tetracarboxylate, reactions of, 849
- Methyl-1,8-dimethyl-1,8-dihydropyriminazole-4,5-, 6,7-tetracarboxylate, synthesis of, 849
- 2-Methyl-2,4-dimethylpentadiene, styrene copolymerization, 251
- Methyldiphenylamine, condensation with formaldehyde, 699
- Methyl 1,2-diphenylpyrazol-5-one-3-carboxylate, formation of, 833
- 1-Methyl-3,6-endomethylene- $\Delta^4$ -tetrahydropthalic anhydride, preparation of, 835
- Methylene acetate, reaction with phenol, 279
- Methyleneacetone, polymerization of, 562
- Methylene acetone, polymerized, condensations with formaldehyde, 550
- Methylenamines, polymerization of, 686
- Methylene-p-aminophenol, resinification, 688
- Methylenaminophenols, substituted, preparation of, 310
- Methyleneanthrone and quinones, condensation of, 834
- Methylene blue, reaction with polyacrylic acid, 1072
- Methylene chain, influence of, in polymethylene polyesters, 872
- Methylenediamide, resinous derivatives of, 884
- Methylene dibenzyl ether, in electrical insulating material, 986
- Methylene dichloride, reaction with phenols, 393, 394
- Methylenedi- $\beta$ -naphthol, from  $\beta$ -naphthol-formaldehyde reaction, 348
- 3,4-Methylenedioxybenzylidene-glycine, resinification of, 733
- Methylenediphenols, reactions of, 420-422
- Methylene diphenylamine, reaction with sulphur, 1197
- Methylene diphenyldiamine, condensation with phenol, 697, 732
- , preparation of, 697
- Methylene diphenyl ether, in electrical insulating material, 986
- Methylenediphenylimine, from aniline and formaldehyde, 707
- Methylene glycol methyl phenyl ether, reaction of, 280
- Methylene groups in urea resin, 582
- Methyleneketobutanol, formation of, 543
- Methylene ketone, condensations of, 550
- Methylenehydrindone, resinification, 558

- Mineral oils, action of sulphur chloride on, 1290
- , in acetylene polymerization, 149
- , ingredient of mastic composition, 1205
- , in linoleum, 198
- , in phenol-aldehyde resins, 354, 455
- , in rosin plastics, 777
- , rubber substitute from, 1212
- , sulphonated, uses of, 351, 419, 1327
- , variation of m.p. of, 27
- , vulcanisation of, 1212
- Mineral powders, fillers, 332
- Mineral spirits, as solvents, 817, 973, 974
- Mirrors, from urea-formaldehyde resins, 604
- , metallic, alkyl resins in, 869
- Miscibility, of alkyl resins, 942, 943, 973
- , of cumarone resins, 125
- Mixing rollers, use of, 324, 329, 1099, 1277
- Moderator, description of, 179
- Modified alkyl resins, 10, 905-944
- Modified cumarone resins, 118, 119
- Modified fatty acids, 1227
- Modified natural resins, 25, 26, 806, 807, 820
- Modified phenol resins, 395, 399
- Modified phenol-sulphur resins, 1192-1193
- Modified sulphonamid-aldehyde resins, 714, 715
- Modified vinyl resins, 1031, 1032
- Modifier, aniline-aldehyde resins, polyvinyl alcohol, 665
- , biuret-cyanuric acid-formaldehyde resin, casein, 685
- , Carbolites, glycerol, 351
- , chlororubber, camphor, 1108
- , dicyanodiamide-formaldehyde resins, fatty oil acids, 680
- , —, oxalic acid, 680
- , —, phenol, 680
- , —, proteins, 680, 681
- , formaldehyde-acetone resins, rubber, 435
- , formaldehyde-furfural resins, rubber, 435
- , phenol-aldehyde resins, acetanilide, 429
- , —, Albertol resins, 397
- , —, alkyl resins, 428, 430, 445

## Modifier, phenol-aldehyde resins, anisole, 431

- , alcohols, 352, 427-430, 439
- , basic carbonates, 435, 438
- , basic oxides, 435-438
- , camphene, 433
- , camphor, 428, 430, 441
- , carbohydrates, 429, 430
- , castor oil, 406, 419, 439
- , cellulose derivatives, 317, 430, 432-434
- , chlorohydrins, 429
- , chlororubber, 435, 436, 1125, 1126
- , p-dichlorobenzene, 433
- , dicyanodiamide, 680, 681
- , drying oils, 402, 404, 405, 407-409, 433
- , dyestuffs, 442
- , esters, 399, 400, 411, 424, 428-433
- , factice, 441
- , formaldehyde-aniline, 423
- , glycerol-glue mixture, 429
- , glycerol resin, 428
- , glycol derivatives, 399
- , inorganic acids, 439
- , inorganic sulphite, 420
- , iodoform, 431
- , Japanese lac, 398, 399
- , ketones, 428, 431
- , leather scrap, 418
- , metallic hydroxides, 435-438
- , metal oxides, 437, 438
- , naphthalene, 440
- , natural resins, 396-402, 408, 426, 437
- , natural waxes, 426, 438
- , nitrobenzene, 440
- , organic acids, 424, 438-440
- , petroleum derivatives, 426, 427, 435
- , phenylphthalimide, 423
- , polyalkylene aryl ethers, 430
- , polycumaron, 397
- , polyethyleneglycol acetate, 430
- , polynuclear phenol, 408
- , polyvinyl alcohol, 665
- , polyvinyl esters, 445
- , proteins, 317, 430, 678
- , rubber, 428, 432, 434-436
- , soaps, 400, 424, 437, 438
- , sodium borate, 437
- , sodium glycerate, 429
- , sulphonated derivatives, 419, 420
- , sulphur, 430
- , turpentine oil, 419
- , wax acids, 427
- , xylene, 440
- , phenol-formaldehyde resins, alcohols, 416
- , alginic acid, 414, 417, 418
- , carbohydrates, 414
- , cellulose, 415
- , cholesterol, 414
- , cyclohexanol, 417
- , esters, 414
- , glue, 414-417
- , glycerol, 414, 416
- , ivory, 418
- , natural resins, 414
- , protein, 414-417
- , vegetable ivory, 414, 416
- , phenol-ketone resins, casein, 417
- , lignite-extract, 427
- , phenol-sulphur chloride resins, dimethylolurea, 672
- , polyvinyl acetals, amines, 1064
- , casein, 1064
- , phenol, 1064
- , urea, 1064
- , polyvinyl alcohol, fatty oil, 1060
- , gelatin, 1064
- , organic acids, 1058
- , syntans, amido derivatives, 420
- , ammonia, 420
- , carbohydrates, 421
- , cyclohexylamine, 420
- , 1,4-diaminoanthraquinone, 442
- , fluosilicates, 421
- , levulinic acid, 421
- , polysulphides, 420

## Modifier, syntans, salicylaldehyde, 421

- , sulphite liquor, 421
- , thiocyanates, 420
- , tar oil hydrocarbon-acetone resins, 389
- , thiourea-aldehyde resins, casein, 680
- , dicyanodiamide, 680
- , urea-alcohol resins, toluene sulphonamide, 664
- , urea-aldehyde resin, acetaldehyde, 671
- , acetamide, 683, 684
- , agar-agar, 683
- , alcohols, 665-669
- , alginic acid, 685
- , aniline, 678
- , carbohydrates, 683-685
- , cellulose, 684, 685
- , chlorinated rubber, 684, 1126
- , dicyanodiamide, 680
- , glycol derivatives, 678, 684
- , guanidine, 682
- , gum tragacanth, 683
- , hexamethylenetetramine, 678
- , itaconic acid polymer, 632, 1086
- , naphthoic acids, 678
- , naphthylamine, 678
- , natural resins, 683
- , natural wax, 685
- , phenol-hexamethylenetetramine resin, 678
- , phenols, 674, 675, 678
- , phthalic anhydride, 663
- , polymerized acrolein, 632
- , polymerized vinyl, 632
- , polyvinyl alcohol, 665
- , proteins, 678-680, 683-685
- , salicylates, 678
- , sulphides, 682-684
- , sulphur, 682, 683
- , tannin, 678
- , p-toluene-sulphonamide, 633
- , urethan, 682
- , xanthates, 682, 683
- , urea-furfural resins, amines, 669
- , camphor, 669, 670
- , lanolin, 670
- , tung oil, 670
- , urea-phenol-aldehyde resins, albumin, 676
- , camphor oil, 674
- , guanidine carbonate, 675
- , oleic acid, 674
- , stearic acid, 674
- , p-toluenesulphonamide, 676
- Modulus of elasticity, determination of, 1341
- Modulus of rupture, determination of, 1342
- Molasses, extraction of, 762
- , fermented, action on petroleum oil, 230
- , reaction with rosin, 796
- , urea and aldehydes, 757
- Molding apparatus, cleaning of, 1332
- Molding compositions, methods of mixing, 1277-1279
- Molding equipment, 1294
- Molding, of dental plates, 464, 465
- , of granulated material, 1320
- , of hollow articles, 1324
- , of large articles, 1332, 1333
- , of phonograph records, 464, 1334-1339
- , of powdered material, 1320, 1321, 1323, 1326, 1327
- , of printing plates, 464
- , of radio-tube bases, 1332
- , of sheet material, 1320
- , of striated articles, 1320, 1321
- Molding presses, types of, 1304
- Molding pressures, for high-impact materials, 462
- Moldings, asbestos-filled, properties, 1273
- , binders for, 1271
- , blistering of, 1320, 1328, 1329
- , coating with metals, 454
- , colored, 22, 483, 484, 1267, 1268, 1276, 1332
- , containing acrylic acid derivatives, 1076, 1078, 1081
- , alkylid resins, 873, 879, 916, 917, 927, 928, 930, 931, 935
- , amine-aldehyde resins, 696, 697

- Moldings, containing Aroclors, 1150  
 —, — butadienol esters, 152  
 —, — carbohydrate resins, 760, 761  
 —, — Carbolites, 351  
 —, — casein-methylol butyl urethan, 682  
 —, — cashew-shell oil, 1230

 —, — of glycerol phthalate intermediates, 866  
 —, — of  $\alpha$ -hydroxydecanoic acid ester, 75, 1002  
 —, — of indane polymer, 100, 101, 103  
 —, — of isobutylene polymer, 166  
 —, — of lactic acid lactide polymer, 1001  
 —, — of Novolak, 305  
 —, — of phenolphthalein toluates, 1263  
 —, — of phenylmicon trichloride resin, 1258  
 —, — of polyester fibers, 1003  
 —, — of polyethylene oxide, 991

- Molecular weight, of polypropylene oxides, 991  
 —, of polystyrene, 75, 235, 238  
 —, of polyvinylacetate, 75  
 —, of  $\alpha$ -n-propyl- $\delta$ -valerolactone polymer, 1001  
 —, of proteins, 67, 68  
 —, of rubber, 75, 1090, 1096  
 —, of shellac salts, 1006  
 —, of silicon ester gels, 1236  
 —, of sulphur dyes, 1153  
 —, of triacetyl cellulose, 75  
 —, of urea resin, 581  
 —, of vinyl ether polymers, 1010  
 Molecular weight and condensation, correlation of, 872  
 Molecular weight and fiber structure, correlation of, 872, 873  
 Molecular weight and property of cold-drawing of filaments, correlation of, 872  
 Molecular weight and property of spinning of filaments, correlation of, 872  
 Molecular weight and specific viscosity, relationship between, 72, 73  
 Molecular weight determination, through diffusion, 67  
 —, — estimation of end groups, 72, 75  
 —, — osmotic pressure, 75  
 —, — specific viscosity, 72, 73  
 —, — ultracentrifugal method, 64, 67, 75, 1002  
 Molecules, folded, 70  
 —, coiled, 70  
 Moloxide, of styrene, 240  
 Molybdenum oxide, catalyst, separation of styrene, 254  
 Molybdenum carbonyl, catalyst, diene polymerization, 184  
 Monel metal screens, use, in drying molding composition, 622  
 Monoacetin, from glycidol acetate, 994  
 —, rosin esters with, 801  
 Monoanhydride of lactic acid, structure of, 1003  
 Monoanilide, formation of, 998  
 Monobasic acids, influence of, in alkyd resin formation, 864, 905, 970  
 Monobasic monoglyceride, use of in alkyd resins, 926  
 Monobenzylidenacetone, resinification, 562  
 Monobromacrylic acid, preparation of, 1079  
 Monobromoisoprene, preparation and properties of, 170  
 Monobromovinylacrylic acid, polymerization of, 1085  
 Monobutylamine butylphthalate, properties of, 954  
 Monochloracetylene-aniline condensation, 1138  
 Monochlorobenzene, use as solvent, 966  
 Monochlorocyclohexane, preparation of, 167  
 Monochlorodimethyl ether, reaction with polyvinyl alcohol, 1068  
 —, — phenols, 280  
 Monochloroethylene, hydrolysis of, 1054  
 Monochloroethylene, reaction with chloroform, 1140  
 $\alpha$ -Monochlorohydrin, reaction, with sodium adipate, 668  
 Monochloronaphthalene as carbon remover, 1154  
 —, in phenol-aldehyde resins, 423, 424  
 Monochlorophenol, reaction with formaldehyde and hexamethylenetetramine, 378  
 Monochloropolyethylene derivatives, preparation of, 167  
 Monochloro-tri (cyclohexanoxo)-silicon, preparation and properties of, 1237  
 Monochlorourea, reaction with aldehydes, 574  
 Monocyclohexylidene-cyclohexanone, from cyclohexanone, 553  
 Monoester formation in alkyd resins, 864  
 Monoethanolamine, catalyst, phenol-formaldehyde reaction, 347  
 —, reaction with monomethylolurea, 667  
 Monoethyldiene compound, from aniline-o-sulphonamide with acetaldehyde, 718  
 Monoethyl ether of diethyleneglycol, *see* Carbitol, 829  
 Monoethyl ether of ethylene glycol, vinyl compounds from, 1007  
 Monoethylin phthalate, in cellulose acetate lacquers, 900  
 Monoethyl oxalate, ethylene oxalate from, 1001  
 Monoglycerides in alkyd resins, 926  
 Monoglycerides of drying oils, preparation of, 928  
 Monoglycerol dipthalate, formation of, 864  
 Monoglycerol monophthalate, formation of, 864  
 Monomethylolacetophenone, preparation of, 556  
 Monomethylolurea, in urea resin condensation, 586  
 —, preparation of, 543, 577, 578, 592  
 —, reactions of, 578, 592, 666, 667  
 Mono-methylxylene-sulphonamide, as plasticiser, 720  
 Monohydric alcohol esters of drying oils, nature of drying of, 920  
 Monohydric alcohols, in alkyd resins, 902  
 —, in castor oil-maleic compositions, 909  
 —, in rosin esterification, 792, 793, 797-799  
 —, in wax esterification, 814  
 Monohydroxyacetone (acetol), polymerization of, 542  
 Monohydroxydiphenylmethanes, preparation of, 295  
 Monolefin-diolefin co-polymerization, *see* Diolefin-monoolefin co-polymerization.  
 Monoolefins, polymerisation of, 164, 225  
 —, polymerization with cyclohexane, 194  
 —, — diolefins, 189-193  
 —, separation of, from diolefins, 184  
 Monolinolein, in alkyd resin production, 929  
 Monomeric adipic anhydride, structure of, 996  
 —, reaction with aniline, 998  
 Monomeric ester from ethylene glycol and oxalic acid, 862  
 Monomeric ethylene oxalate, formation of, 871  
 Monomeric glycol carbonate, formation of, 870  
 Monomeric propylene glycol oxalate, formation of, 871  
 Monomeric resin, examples of, 14  
 Monomolecular films, of fatty acids, 40  
 —, of polymers, 40, 41  
 —, nature of, 40  
 Monophenyl germanium, formation of, 1239  
 —, polymerization of, 1239  
 Monothioaldehyde, preparation and properties of, 1180  
 Monovalent-polyvalent phenol mixtures, condensation, with formaldehyde, 372, 373  
 Monovinylacetylene, *see* Vinylacetylene  
 Monovinyl ether of diethanolamine, preparation of, 1007  
 Montan wax, halogenation of, 219, 220, 1154  
 —, esterification with glycerol, 814  
 —, hardened, 773  
 —, flooring compositions from, 983  
 —, impregnants from, 1245  
 —, in alkyd resins, 911, 948  
 —, in chlororubber, 1123  
 —, in coal-tar bitumen compositions, 360  
 —, incorporation with iron, 211  
 —, in phenol-aldehyde resins, 426, 433  
 —, insulating cement, 820  
 —, in urea-aldehyde resins, 685  
 —, lubricant for molding composition, 983  
 —, modifications of, 814, 815  
 —, oxidation of, 209  
 —, polishes from, 814, 993  
 Montan wax-acid esters, uses of, 828, 829  
 Montan wax acids, esterification of, 815  
 Montan wax alcohols, esterification of, 814, 815  
 Mortants, from amine-aldehyde resins, 701  
 —, phenol-aldehyde resins, 340  
 —, phenol-sulphur resins, 1183, 1190-1192  
 —, urea-phenol-aldehyde resins, 676  
 Mother of pearl, substitute, 591  
 Moth-repellants, from formaldehyde-chlorophenols, 378  
 Motion picture films, from polyvinyl ester-acetals, 1067  
 Mottled articles, by injection molding, 1335  
 Mottled articles, molding of, 1320, 1321  
 Mottled effect in floor tile, 138  
 Motor-fuels, action on chlororubber films, 1123  
 —, from naphthalene-olefin condensation, 194  
 —, from cumarone polymerisation, 116

- Mounting, of radio transformers, 1313  
 Mucic acid, in urea-formaldehyde condensate, 610  
 Mucilage, glycerol-boric ester in, 893  
 Mucin, intestinal, in phenol-formaldehyde resins, 414, 417  
 Muconic acid and butadiene, reaction between, 834  
 Muconal-dialdehyde, polymerisation of, 507  
 Mud, use with resins, 1250  
 Muffles, of synthetic resin, 1250  
 Multi-colored moldings, 1314, 1325, 1333  
 Multicondensation, classification of, 54, 55  
 —, nature of, 42, 54  
 Multiple-cavity molds, 1294, 1325, 1332  
 Multiple cylinder pumps for hydraulic presses, 1308  
 Multiple-platen presses, operation of, 1306  
 Multiples in polypeptides, 67  
 Munitions, phenol used in, 359  
 Muscle protein, nature of, 68  
 Musk, composition of, 998  
 Mustard oils, thioureas from, 652  
 Myrcene and crotonic aldehyde, reaction of, 843  
 Myrcene and maleic anhydride, reaction of, 843  
 $\beta$ -Myrcene, from isoprene, 51, 172
- N
- Nail coating from cumarone resin, 129  
 "Nail test" of cumarone resins, 124  
 Naphtha, coal-tar, cumarone resins from, 106-120  
 —, —, determination of resin-forming material in, 107  
 —, —, drying of, 108  
 —, —, purification of, 109, 114, 115, 117, 118  
 —, —, —, by bromination, 116, 117  
 —, —, —, by chlorination, 109, 117  
 —, —, removal of bases from, 108, 114, 116  
 —, —, removal of phenols from, 107, 108, 114, 116  
 —, phenol-containing, cumarone resins from, 119  
 —, production of cumarone resins from, 106-120  
 —, refining of, 227  
 —, removal of indene, 106  
 —, removal of tar acids, 107  
 —, rosin solutions in, 770  
 —, rubber solvent, 1092  
 —, solvent, cold-molding compositions, 1285  
 —, —, condensation with benzaldehyde, 265  
 —, —, formaldehyde-wood-tar-phenol resin, 365, 366  
 —, —, petroleum resins, 204  
 —, —, resin from cracked-gasoline polymerization, 192  
 $\alpha$ -Naphthaldehyde, resinification of, 510  
 Naphthalene, action of chloral on, 263  
 —, action of formaldehyde on, 263, 264  
 —, action of hydrogen peroxide on, 269  
 —, action of methylal on, 263  
 —, action of oxalic acid and aluminum chloride on, 266  
 —, alkylation of, 194  
 —, chlorinated, condensation medium, 617  
 —, —, modifier, 404  
 —, chlorination of, 220, 1136, 1137, 1142, 1150, 1151  
 —, condensation products from, in tanning agents, 267  
 —, condensation with olefins, 194  
 —, copals treated with, 809  
 —, decomposition products of, 268  
 —, electrolytic oxidation, 268  
 —, fluorinated, 1156  
 —, from by-product coke ovens, 360  
 —, from styrene, 238  
 —, halogenated, plasticiser, urea resins, 617  
 —, hydrogenated, condensation medium for urea resins, 617  
 —, —, condensation with olefins, 194  
 —, introfiter for sulphur, 1165  
 —, modifier, phenol-aldehyde resins, 440  
 —, nitrated, condensation medium for urea resins, 617  
 —, —, oxidation of, 263  
 —, —, plasticiser, 447  
 —, —, cellulose acetate-urea resin composition, 623  
 —, —, polyvinyl chloride, 1033  
 Naphthalene, polychlorinated, softening agent, phenol-aldehyde resins, 424  
 —, preparation of resin from, 266  
 —, products of hydrogenation, 268  
 —, reaction with benzal chloride, 1134  
 —, —, chlorinated lard oil, 1158  
 —, —, chlorinated wax, 1140  
 —, —, chlorosulphonic acid, 584  
 —, —, ketene, 554  
 —, —, sulphur monochloride, 1202  
 —, removal from coal-tar naphtha, 108  
 —, resin from, 265, 266, 269  
 —, resinified by hydrosilicates, 1137  
 —, resinous by-products from purification of, 120  
 —, retarder, alkyl resins, 881  
 —, softener, phenol-aldehyde resins, 423  
 —, —, rubber products, 1098  
 —, solvent, polyvinyl chloride, 1038  
 —, sulphonated, condensation with acetone, 541  
 —, use of, 332, 349  
 Naphthalene derivatives as lacquers, 1137  
 Naphthalene dichloride, 1136  
 Naphthalene-2,7-disulphonic acid, tars from, 1202  
 Naphthalene-ethylene condensation, catalysts for, 194  
 Naphthalene-formaldehyde resin, 263, 264, 265  
 Naphthalenemonosulphonamide-aldehyde resin, lacquers from, 717  
 Naphthalene oil, condensation products from in tanning agents, 267  
 Naphthalenesulphonamide, reaction with formaldehyde, 712  
 Naphthalenesulphonic acid, catalyst, phenol-formaldehyde reaction, 352  
 —, reaction with sulphur, 1202  
 —, reaction with hydroxybenzyl alcohol, 419  
 Naphthalenesulphonic acid-formaldehyde product, 267, 1193  
 Naphthalenesulphonyl chloride, reaction with sodium colophonyl, 1206  
 Naphthalene-sulphur resins, 1202, 1212  
 Naphthalene tetrachloride, incorporation with phenol-rubber product, 1104  
 —, resinification of, 1136  
 Naphthalene-xylyl chloride condensation, 1131  
 Naphthalic acid, condensation with polyhydroxy acids, 910  
 —, modifier, phenol-aldehyde resins, 439  
 1,8-Naphthalic acid, use in alkyl resins, 883  
 Naphtha sulphonic acid, catalyst in formation of phenol-glycerol resins, 393  
 Naphthazarine, reaction with butadiene, 834  
 Naphthenate driers, 785, 786  
 Naphthenates, polymerization catalysts, 207  
 —, oxidation of, 217  
 Naphthenes, reaction with formaldehyde, 212  
 —, sulphonation of, 217  
 Naphthenic acid chlorides, reaction with polyvinyl alcohol, 1099  
 Naphthenic acid glycerides, in coatings, 828  
 Naphthenic acids, action on amines, 208  
 —, action on amino-alcohols, 207  
 —, combination with polyvinyl acetate, 1032  
 —, driers from, 785  
 —, from alkali sludge, 205, 206, 207  
 —, from petroleum, 203, 205, 208  
 —, lacquers from, 207  
 —, modifiers, phenol-aldehyde resins, 439  
 —, oxidation of petroleum, 208  
 —, oxidation of turbine oil, 209  
 —, reaction with rosin, 803  
 —, resins from, 207  
 —, sulphurized, in varnishes, 1210  
 —, use in vulcanization of sodium-butadiene rubber, 196  
 Naphthenic acid salts, 783, 784  
 Naphthenic anhydrides, action on cellulose, 208  
 $\alpha$ -Naphthol, action of lead oxide on, 273  
 —, condensation, with 2-aldehyde-4-methyl-phenoxycetic acid, 375  
 —, condensation with diphenylformamidene, 395  
 —, glyceride oils modified with, 1227  
 —, inhibitor, 408  
 —, in tar acids, 361  
 —, reaction with benzaldehyde, 279

- $\alpha$ -Naphthol, reaction with benzyl chloride, 1133
  - , — cyclohexanone and formaldehyde, 390
  - , — hexamethylenetetramine, 308
  - , — sulphur dichloride, 1184
- $\alpha$ -Naphthol-acetaldehyde reaction, 283
- $\alpha$ -Naphthol-benzotrichloride reaction, 1135
- $\alpha$ -Naphthol-formaldehyde resin, 284
- $\alpha$ -Naphthol-furfural, resin from, 525, 530
- $\alpha$ -Naphthol-lead oxide resin, 273
- 1-Naphthol-6-sulphonic acid, condensation with rosin, 800
- $\beta$ -Naphthol, action on furfural, 519
  - , chlorination of, 1184
  - , condensation with diamines, 732
  - , — diphenylformamidine, 395
  - , — p-nitrobenzaldehyde, 295
  - , crystallization inhibitor, 787
  - , effect on drying rate of oils, 408
  - , effect on polymerization of tung oil, 1217
  - , in tar acids, 361
  - , plasticizer, alkyl resins, 890
  - , reaction with formaldehyde, 295, 343, 408
  - , — hexamethylenetetramine, 308
  - , — sulphur dichloride, 1184
  - , resinification, with carbon dioxide, 374

  - , —, vinylthiaryl-carbinol polymers, 151

- Nitrocellulose, compatibility with xylenol ether-formaldehyde resin, 371  
 —, cottonseed oil modified alkyd resin with, 906, 966  
 —, cumarone resin with, 970, 1243  
 —, double refraction of, 33  
 —, ester gum with, 797, 816, 822-829  
 —, ethyl abietate with, 823  
 —, filler, phenol-aldehyde resins, 318  
 —, incorporation with polyvinyl halide, 1043  
 —, incorporation with urea resins, 623, 624, 637, 644, 645  
 —, ketone-furfural resins with, 447  
 —, linoxyn with, 1234  
 —, metallic alkyl phthalates with, 952  
 —, modifier, phenol-aldehyde resins, 317, 433  
 —, nitrated castor oil with, 1223  
 —, Olovine with, 1227  
 —, oxidizing alkyd resins with, 972, 978  
 —, paraffin with, 1243  
 —, phenol-o-benzoylbenzoic acid resin with, 433  
 —, phenol resin varnishes with, 446, 447  
 —, Plastopals with, 634, 635  
 —, proportion with Reszyls, 956  
 —, reduction of inflammability of, 447, 913  
 —, Reszyls as preservatives for, 966  
 —, rosin-maleic-glyceride with, 837  
 —, sulphonamide resins with, 717, 718  
 —, urea resin lacquers with, 634-638  
 —, use in cementing composition, 939  
 —, use in flooring compositions, 983, 984  
 —, use in leather dressings, 967  
 —, use in linoleum, 199  
 —, use in linseed oil lacquer, 825  
 —, use in Teglac compositions, 912, 913  
 —, varnish gums with, 951  
 —, waxes with, 1243  
 —, zinc n-butyl phthalate with, 950  
 Nitrocellulose coatings, standards, for gloss of varnish, 1370, 1371  
 Nitrocellulose compositions, for waxed paper, 984  
 —, protective coatings from, 966, 967, 1377  
 Nitrocellulose films, blushing, nature of, 913  
 —, plasticizers for, 970  
 —, prevention of blushing, 968  
 Nitrocellulose lacquers, alkyd resins in, 10, 874, 875, 903, 908  
 —, ammonia in, 1210  
 —, butyl alcohol with, 412  
 —, hydroquinone as oxidation inhibitor, 823  
 —, isopropyl alcohol with, 966  
 —, linseed oil in, 1228  
 —, metallic soaps in, 738  
 —, polyacrylic acid chloride for, 1075  
 —, polymers of acrylonitrile in, 1076  
 —, polyvinyl acetate with, 1027  
 —, preparation of, 822  
 Nitrocellulose plasticizers, alkyd resins, 901  
 —, dibutyl-3,6-endomethylene- $\Delta^4$ -phthalate as, 836  
 Nitrocellulose plastics, crotonic-glycerol esters in, 1082  
 Nitrocellulose substitute, alginate nitrate, 1254  
 Nitrochitin acetate, preparation, 1255  
 6-Nitro-3-chloroaniline, tars from, 739  
 p-Nitrochlorobenzene, condensation with aldehydes, 726  
 Nitrochloroethylene, polymerization, 1042  
 o-Nitrocinnamylglycol nitrile, reaction, 726  
 Nitro-compounds, tars from, 735, 736  
 Nitrocelophony, 730  
 Nitroresol, condensation with phenol alcohols, 287, 288  
 Nitrocumarones, preparation of, 94  
 6-Nitro-3,4-dichloroaniline, tars from, 739  
 o-Nitrodiphenylarsinic acid, preparation, 727  
 o-Nitrodiphenyl ether, combination with polyvinyl chloride, 1044  
 Nitrogen, catalyst, acrylic acid polymerisation, 1070, 1071  
 —, effect on acetylene polymerization, 146  
 —, elimination of, 829  
 —, in ammonia production, 568  
 —, test for, in resins, 1233  
 —, use of, 353  
 —, use in alkyd resin production, 923, 933  
 Nitrogen, use in light colored resins, 968  
 —, use in polymerization of 1,3-dienes, 183  
 —, use in polymerization of glycerol, 966  
 Nitrogen bases, conversion of wax esters to amides, 815  
 —, removal from coal-tar fractions, 361  
 Nitrogenous material, removal of, from rubber, 1007  
 Nitrogen oxides, reaction with phenanthrene, 724  
 —, reaction with unsaturated distillates, 728  
 Nitrogen pentoxide, reaction with stilbene, 734  
 Nitrogen peroxide, action on rubber, 1094  
 —, catalyst, polycyclopentadiene formation, 188  
 —, from nitric oxide, 188, 728  
 —, reaction with p-cresol, 725  
 —, reactions with unsaturated hydrocarbons, 727  
 Nitrogen sulphide, action on pinene, 1200  
 Nitrogen tetroxide, reaction with aromatic hydrocarbons, 724  
 Nitrogen trioxide, effect on polycyclopentadiene, 188  
 —, reaction with phenylcyclohexanone, 725  
 Nitro-hydrocarbons, solvents, polyvinyl esters, 1025  
 2-Nitro-2-(hydroxymethyl)-1,4-butandiolone, reannilation of, 511  
 Nitrolignin, polymerization, 729, 730  
 Nitromethane, solvent, polyvinyl acetate, 1026  
 2-Nitro-6-methyldiphenylamine-6'-arsinic acid, re-sulfonation, 727  
 o-Nitrophenol, modifier, oxidized fatty acids, 1227  
 —, reaction with furfural, 525  
 —, reaction with p-nitrobenzaldehyde, 383  
 p-Nitrophenol, reaction with formaldehyde, 294  
 —, reaction with hexamethylenetetramine, 208  
 p-Nitrophenylcarbamide, polymerization, 727  
 p-Nitrophenyl-sulphur chloride, action on rubber, 1101  
 Nitrophenylurea, reaction with chloral hydrate, 576  
 3-Nitrophthalic acid, use in alkyd resins, 954  
 Nitropiperonal, reaction with piperidine, 738  
 —, resins from, 726  
 1-Nitro-1-propene, polymerization, 726  
 Nitro resins, 724, 728-730  
 —, from petroleum oil, 728, 729  
 —, rubber substitute, 729  
 Nitrosite of cumarone, 94  
 Nitrosite of indene, 98  
 Nitrosoacetanilide, action of alkali, 734  
 Nitrosobenzene, reaction with rubber, 1095  
 Nitroso compounds, removal of hydrogen sulphide by, 652  
 Nitrosodimethylaniline, reaction with rubber, 1095  
 Nitrosodiphenylamine, with acetic acid, reaction with tung oil, 1217  
 1-Nitroso-5-phenylpyrazoline, reaction with acids, 736  
 Nitrostyrene, polymerization of, 259  
 Nitro-substituted benzenes, condensation with butadiene, 194  
 Nitrosyl bromide, in lactone formation, 1141  
 Nitrosyl chloride, action on benzene, 1141  
 —, catalyst polymerization of isoprene, 174  
 —, reaction with acetone, 725  
 —, reaction with benzene, 724  
 o-Nitrotoluene-p-sulphonyl-p-anisidine, tars from, 724  
 Nitrous acid, action on cumarone, 94  
 —, action on indene, 98  
 —, prevention of varnish-yellowing, 1373  
 —, reaction with d-neomenthylamine, 725  
 —, use in rearrangement of geometric isomers, 908  
 Nonaldehyde, condensation with, aniline, 705  
 Nonamethylene carbonate, dimer of, 870  
 Nonacetyne, formation of, 162  
 Nonate of castor oil fatty acids, 1224  
 Non-blistering paint, 1236  
 Non-blushing nitrocellulose lacquer, composition of, 970  
 Non-breakable sound records, manufacture, 1335, 1336  
 Non-convertible alkyd resins, properties of, 963, 974  
 Non-drying alkyd resins, 874, 875  
 Non-drying ink, cumarone resin in, 140  
 Non-drying oil acids, use in alkyd resins, 905-917

- Non-drying oils, conversion to drying oils, 1225  
 —, use in alkyd resins, 905-917, 937
- Non-inflammable fibers, urea-formaldehyde resins, 588
- Non-metallic halides, action on rubber, 1100-1101
- Nonhatterable glass, requirements for, 1212
- Non-splintering glass, components of, 963
- Non-static photographic films, coatings for, 827
- Non-volatile matter in varnishes, determination of, 1363, 1364
- Norcamphor, synthesis of, 834, 835
- Norcantharidin, synthesis of, 846
- Notched specimens for impact testing, 1342
- Novolaks, action of Grignard reagent on, 305  
 —, coating composition from, 447  
 —, defined, 315  
 —, from p-cresol and formaldehyde, 304  
 —, from 2,6-dimethylphenol, 301  
 —, hardening of, 353  
 —, modification with linseed oil, 405  
 —, production, 296, 323, 348, 349  
 —, structure of, 303-306, 309
- Nuclei formation, in supercooled melts, 29
- Nuclei formation, processes in, 30
- ( )
- Oat hulls, furfural from, 517  
 —, reaction with phenol, 748
- Ochre, use in linoleum, 198  
 —, — polyvinyl laquers, 1026
- Octabenzylallicotetrane, 1238
- 9,11-Octadecadiene-1-carboxylic acid, and ester gum in printing ink, 827  
 —, preparation of, 927, 962  
 —, use in alkyd resins, 927
- Octadecadienoic acid, preparation of, 1224, 1225
- Octadecanol, use in castor oil-maleic compositions, 909
- Octahydroanthracenesulphonic acid, modifier, phenol-aldehyde resins, 419
- $\Delta^{2,6}$ -Octahydroanthraquinone, preparation of, 832
- Octahydroanthraquinones, isomerization of, 834
- 2,3,6,7,2',3',6',7'-Octamethyl-10-10'-dihydro-dianthrol, formation of, 833
- Octamethylene carbonate, dimer of, 870
- Octamethyltetrahydrobipyridyl, 737
- Octane, reaction with sulphur, 215
- 1-2-Octanol reaction with p-toluenesulphonyl chloride, 723
- Octaphenylcyclooctatetraene, 1237, 1238
- 2,4,6-Octatrienal-1, phenylhydrazones, resinification of, 510
- 1,5,7-Octatriene-3-yne, formation of, 143
- 1-Octene-3,7-dione, 550
- Octenes, of isomeric butenes, alkylated phenols with, 411
- 2-Octyl-p-toluenesulphonate, from p-toluenesulphonyl chloride and 1-2-octanol, 723
- sec.-Octyl toluyl-o-benzoic acid, metallic salts of, 953
- 1-Octyne, polymerization of, 162
- Odor, o-cresol-formaldehyde resin, 367  
 —, cyclic anhydrides, 998  
 —, molded objects, 23  
 —, resins, detection, 1259  
 —, varnish solvents, 21
- Offset ink, drying alkyd resins in, 979
- Offset rolls, use of alkyd resin in making, 989
- Oidium, fungus, destruction of, 1186
- Oil, dielectric strength tests in, 1372  
 —, drip, indene from, 97  
 —, —, styrene from, 97  
 —, sesame, with cumarone resin, 135  
 —, vulcanized, with cumarone resin, 136
- Oil black, chlororubber paint, 1120
- Oilcloth, coating composition for, 820, 1209  
 —, cumarone resin in manufacture of, 136, 137  
 —, from styrene with cellulose ester plastics, 249  
 —, manufacture of, 136, 137  
 —, resin oil in, 778
- Oil enamels, superiority of synthetic resin enamels, 974
- Oil-modified alkyd resins, coating compositions, 963, 970, 977, 978  
 —, molded insulation material, 996
- Oil modified alkyd resins-nitrocellulose lacquer, molded articles, 967
- Oil-modified phenol resins, 402-406  
 —, uses of, 403, 404, 466
- Oil-modified resin, 693
- Oil of anise, resinification, 1253  
 —, cassia, reaction with phenols, 383  
 —, cumarian, reaction with phenols, 383  
 —, juniper, resin from, 1253  
 —, lavender, resin from, 1253  
 —, rue, resin from, 1253  
 —, sweet almonds, resin from, 1253  
 —, turpentine, resins from, 1253  
 —, solvent, for  $\alpha$ -naphthol-formaldehyde resin, 284  
 —, wintergreen, resin from, 1253
- Oil paintings, impregnated backings, 1246
- Oil paints, alkyd resin in, 977
- Oil-phenol mixtures, sulphonated, reaction, with aldehydes, 421
- Oilproof paper, from chloroprene rubber, 159
- Oil-refining residues, treatment with olefins, 195  
 —, vulcanization of, 1204
- Oil-reactive phenolic resin combinations, 934
- Oil-resin varnish films, absorption of actinic rays by, 977
- Oil-resistance, casein-modified phenol-formaldehyde resin, 417  
 —, cashew shell liquids, 1232  
 —, tests for varnishes, 1365, 1366
- Oil-resistant packing, with phenol resins, 485
- Oil-resistant varnish cloths, use of alkyd resins, 874
- Oils, action of sulphur chloride on, 216  
 —, action on chlororubber, 1125  
 —, aqueous solvent for, 1210  
 —, chlorinated, preparation of, 1155, 1220, 1221  
 —, 1-chloronaphthalene-formaldehyde resin as solvent for, 266  
 —, coal-tar, decolorization of, 261  
 —, —, precipitation of aldehyde-tar-acid resins from, 364  
 —, —, purification of, 361  
 —, —, reaction with aldehydes and ketones, 363  
 —, cracking of, 221, 222  
 —, dechlorinated, compounded with rubber, 221  
 —, deterioration, effect of aldehyde-amine products, 711  
 —, drying, solubility of cumarone resins in, 125  
 —, drying of, effect of phenol-aldehyde resins on, 413  
 —, drying rate of, effect of  $\beta$ -naphthol, 408  
 —, effect, in phenol-aldehyde resin, 320  
 —, essential, cymene from, 1253  
 —, extending agents, for phenol-aldehyde resin, 283  
 —, fatty, in cellulose-ester varnish, 1244  
 —, —, solubility of phenolic resins in, 271  
 —, flavoring with cumarone resin, 134  
 —, for factice, 1312  
 —, for therapeutic purposes, from tar oil hydrocarbons, 276  
 —, from action of aldehydes on coal-tar fraction, 120  
 —, from polymerization of butadiene hydrocarbons, 172, 173, 185  
 —, —, olefins, 165, 166  
 —, from reduction of rubber, 1097  
 —, hydrogenation of, 221  
 —, in plastic composition, 826  
 —, in rubber surfacing composition, 1092  
 —, limed, reaction with sulphur, 1213  
 —, lubricating, cumarone resin with, 140  
 —, mineral, in cellulose-ester varnish, 1244  
 —, —, resistance of Glyptal resins to, 955  
 —, non-drying, use with polyvinyl ester-acetals, 1067  
 —, plasticizers, for synthetic resins, 1246  
 —, properties of, by formolite numbers, 218  
 —, reaction with sulphonated chloroacetone-phenol resin, 421  
 —, removal from phenol-aldehyde resins, 362  
 —, resinified by cobalt linoleate, 229  
 —, —, potassium thiocyanate, 229  
 —, solubility of metallic salts in, 963  
 —, use, polishing composition, 1241

- Oils, use, polyvinyl alcohol sizings, 1058  
 —, use of enzyme hydrolysis in fatty, 930  
 Oils and caoutchouc, polymerization of, 229  
 Oil solubility of copal esters, 819  
 Oil-soluble phenol resin, ammonia catalyst, 402  
 —, comparison with ester gum, 409  
 —, non-reactive, 403, 404  
 Oil-soluble phenolic resins, 1133  
 Oil-soluble resin, 390  
 Oil-soluble resins, cresylic acid-formaldehyde, 408  
 —, end-point of fusion of, 397  
 —, insulators, 1182  
 —, phenol-ketone-formaldehyde, 410  
 —, reaction with drying oils, 401  
 —, unmodified, 407-412  
 —, uses of, 401  
 Oil Stop, from cashew shell oil, 1229  
 —, uses of, 1232  
 Oil-storage tanks, coating of, 937  
 Oil-synthetic resin emulsion, in water, 404  
 Oil test cup, for dielectric strength tests, 1373  
 Oil-treated Rezyls, 973  
 Oil varnishes, 19, 21  
 —, copal esters in, 816  
 —, effect of cresol, 408  
 —, from fural-acetone resin, 537  
 —, from phenol-crotonaldehyde resins, 392  
 —, modified polyvinyl esters, 1059  
 —, objections to rosin in, 816  
 Oily substances, from cumarone resin, 116, 118  
 —, from thermal polymerization of acetylene  
 Oiticicia oil, ester gum varnishes, 817  
 —, polymerization of, 1232  
 —, source of, 817, 861  
 —, uses of, 1232  
 Oleate, of castor oil fatty acids, 1221  
 Olefin halides, reactions of, 797, 1169-1172  
 Olefinic substances, removal from benzene, 121  
 Olefin oxides, stabilisers, vinyl resins, 1048  
 —, use, in polymerization of 1,3-dienes, 182  
 Olefin polymerization, 164  
 Olefin polymers, dehydrogenation of, 165  
 —, splitting of, 167  
 Olefin-polysulphide resins, 711, 1173, 1174  
 Olefin polysulphide rubber, 1169, 1173  
 Olefin polysulphides, admixture with other resins, 1176  
 —, effect of chromic acid on, 1175  
 —, — sulphur monochloride-phenol products on, 1173  
 —, hardened by slaked lime, 1174  
 —, incorporation of aldehyde-polysulphides, 1181  
 —, — chlorinated rubber, 1173

 —, — sulphur dioxide, 167  
 —, resinous substances from, 165, 167  
 Olefin selenides, 1170  
 Olefin-sulphide resins, 1170, 1171  
 Olefin-sulphides, combination with rapeseed oil, 1171  
 Olefin sulphones, celluloid substitutes, 1178  
 —, monomeric, x-ray studies, 1178  
 Olefin-sulphur dioxide reaction, effect of light, 1178  
 iso-Oleic acid, by zinc chloride-oleic acid reaction, 1222  
 Oleic acid, chlorinated, 1220  
 —, condensing agent, amines and aldehydes, 707  
 —, effect on chloroprene rubber, 158  
 —, esterification of phenol-alcohols with, 399  
 —, inhibitor, for gelatinization of tung oil, 1216  
 —, isomerization of, 908  
 —, lanolin substitute for, 1212  
 —, modifier, urea-phenol-aldehyde resins, 674  
 —, phenol-aldehyde resins fused with, 398  
 —, plasticizer for oleic resin coatings, 969  
 —, reaction with acetic anhydride, 549  
 —, — aluminum chloride, 1219  
 —, — p-amino-phenol, 1223  
 —, — aniline and paraformaldehyde, 695  
 —, — sorbitol, 1209  
 —, — triethanolamine, 904  
 —, — zinc chloride, 1223  
 —, softener for rubber products, 1098  
 —, solubilization of castor oil with, 1222  
 —, sulphurized, formation of, 1211  
 —, use in alkyd resins, 905, 907, 926, 927, 936  
 —, — amine-aldehyde condensations, 702  
 Oleic acid modified alkyd resin, binder for asbestos cloth, 987  
 —, emulsification, 946  
 Oleic acid modified glycerol phthalate, preparation of, 905  
 Oleic glycerides, in tung oil, 1215  
 Oleic-phthalic glyceride, sulphurization of, 1206  
 Oleone, reaction with hypochlorous acid, 551  
 Oleone chlorohydrin, reaction with soap, 551  
 Oleoresinous primers, comparison with alkyd resin primers, 959, 961  
 Oleoresinous varnishes, coatings for pipes and tanks, 1877, 1878  
 Oleum, condensing agent, ethyl abietate preparation, 798  
 —, used in sulphonation, 1122  
 Olive oil,  $\beta$ -form, use in alkyd resins, 908  
 —, modification, 1237  
 —, use, lubricant, 1237  
 Olovine, 1038, 1237  
 Olovine varnish, from Tekao with polyvinyl ester, 1237  
 One-phase theory of gels, 37  
 One-stage dry processes, 326  
 One-stage wet process, phenol-aldehyde resins by, 322-326  
 Opacity, varnish films, causes for, 20  
 Opacity tests, for varnishes, 1877  
 Optical cement, from vinyl co-polymers, 1082  
 Optical elements, from polystyrenes, 252  
 Optical properties, resins, 770, 1262  
 Optical system, ultracentrifuge, 70  
 Optoquinine sulphate, gels from, 88  
 Orcinol, modifier, urea-aldehyde resins, 674  
 —, reaction with benzaldehyde, 378  
 Organic acid anhydrides, use of, 329  
 Organic acid chlorides, condensing agents, 289, 290  
 Organic acid peroxides, preparation, 1023

- Organic acids, condensing agents for phenol alcohols, 287, 288  
 —, curing catalysts, cellulose-urea resin compositions, 622

 Organic arsenic compounds, wood preservatives, 1165  
 Organic bases, adjusting pH of formaldehyde solutions with, 612  
 —, catalysts, polymerisation of styrene, 242  
 —, reactions with mercapto compounds, 647  
 Organic fillers, for phenol-aldehyde molding powder, 461-463  
 Organic glass, 602, 604  
 Organic peroxides, catalysts, polymerization of acrylic acid, 1075  
 —, —, — divinyl ether, 1011  
 —, —, — methyl methacrylate, 1081  
 —, driers for oil-modified alkyd resin coating compositions, 978  
 Organic phosphates, solubilisation of castor oil with, 1223  
 Organic silicon compounds, 1235  
 Organic silicon radicals, in resins, 1239  
 Organic sulphonic acids, alkylating agents, for abietic acid, 805  
 Organic sulphur compounds, effect on chloroprene polymerisation, 156  
 Organo-metallic compounds, action on unsaturated hydrocarbons, 229  
 Organophilic colloids, 38  
 Ornamental materials, from urea resins, 641  
 Ornamentation, moldings, 1266, 1333, 1334  
 —, rubber, 1333  
 Ornamenting fabrics, with modified urea-aldehyde resin, 685  
 Orthophosphoric acid, catalyst for rosin esterification, 795  
 Orthophosphorous acid, catalyst, esterification of rosin, 795  
 Osborne Reynold's effect, nature of, 32  
 Osmosis, removal of catalyst by, 595  
 Osmotic pressure measurements in molecular weight determinations, 53, 75  
 Ottawa sand, abrasion resistance tests for varnish with, 1366  
 Outdoor exposure tests, varnish film, 818  
 Outside paints, alkyd resins in, 977  
 Overcuring, effect on chloroprene rubber, 158  
 Overheated glycolic acid, adhesive from, 1004  
 Overlays, decorative, application of, 1333  
 Overprint varnish, Rezyls with, 973  
 Oxalate, of polyvinyl alcohol, 1059  
 Oxalic acid, 883  
 —, accelerator, urea resins, 619  
 —, action on rosin, 768  
 —, catalyst, 401  
 —, —, amines and aldehydes, 700  
 —, —, furfural-phenol reaction, 326  
 —, —, glycerol-dimethylolurea reaction, 668  
 —, —, hydrocarbon-aldehyde resin, 265  
 —, —, phenol-aldehyde resin, 285, 349, 369, 411, 429, 431  
 —, —, resin formation, 279  
 —, —, thiourea resins, 640  
 —, —, urea-aldehyde reaction, 589, 663  
 —, —, urea-phenol-aldehyde reaction, 674, 675  
 —, dehydrating agent,  $\beta$ -methylketobutanol, 550  
 —, from polyvinyl alcohol, 1056  
 —, from polyvinyl ethyl ether, 1011  
 —, from rubber oxidation, 1093  
 —, hardening agent, thiourea resins, 654  
 —, modifier, dicyanodiamide-formaldehyde resins, 690  
 —, —, phenol-aldehyde resins, 439  
 —, —, polyvinyl alcohol, 1058  
 —, neutralising agent, 319  
 —, polymerization of dimethylolurea by, 609, 610  
 —, reaction with  $\alpha$ -aminophenol, 690  
 —, —, carbohydrates, 753  
 —, —, castor oil, 906  
 Oxalic acid, reaction with polyhydric alcohols and phenol-aldehyde resins, 428  
 —, treatment of turpentine with, 1201  
 —, use of, 354  
 Oxalic acid and aluminum chloride, action on naphthalene, 266  
 Oxalic acid derivatives, esterification with ethylene glycol, 862  
 —, use as anti-rancification reagents, 909  
 Oxalic acid-pinenes condensation, 783  
 Oxalyl chloride, reaction with 2-methylindole, 743  
 —, —, pyrrole, 742  
 Oxidation, acceleration by driers, 784  
 —, acrolein, 1069  
 —, alkyd resins, 911, 914  
 —, bitumen, 210  
 —, chloronaphthalene waxes, 1152  
 —, contributory cause of gelation of oils, 975  
 —, copals, 774  
 —, cracked distillates, 222  
 —, cracked gasoline, 201  
 —, crude tar oil with lead oxide, 273  
 —, diundene by chromic acid, 105  
 —, asym-diphenylethylene, 259  
 —, electrolytic, cymene, 1253  
 —, —, 4-hydroxy-3-methoxy propenal, 272  
 —, —, isoeugenol-vanillin solution, 262  
 —, fatty oils, 1225  
 —, indene, 100  
 —, lignite, 209  
 —, limonene, 783  
 —, low temperature tar under pressure, 272  
 —, methylindenes, 105  
 —, montan wax, 209  
 —, naphthenes, 217  
 —, paraffin, 209, 217  
 —, petroleum, 208-211  
 —, —, asphalt and pine tar, 230  
 —, petroleum residues, 217  
 —, phenols, 271, 272  
 —, polymerization of fatty oils by, 1225, 1226  
 —, refining residues, 227  
 —, resistance of cumaron- resins to, 125  
 —, rosin, 767, 768, 774, 780  
 —, rosin esters, 806, 807  
 —, rubber, 1109  
 —, —, preventing, 1128  
 —, rubrene, 269  
 —, still residue, 229  
 —, styrene, 239  
 —, sulphite waste-liquor, 754  
 —, tall oil, 755  
 —, tar distillates, 273  
 —, tar oil, 209  
 —, toluene-o-sulphonamide, 712, 713  
 —, urea-phenol-aldehyde resins, 675  
 —, wood oils, 780  
 —, wood tar, 752  
 Oxidation accelerators, catalysts, in polymerization of vinyl ethinyl carbinols, 151  
 Oxidation products of rubber, 1093  
 Oxidation-resistance, of hydroxybenzoic-acid resins, 378  
 Oxide, of polycyclopentadiene, 188  
 Oxide catalysts, condensation of acetaldehyde over, 495  
 Oxides, ability to form glasses, 28  
 Oxides of carbon, lower, formation of, 1014  
 Oxides of nitrogen, action on phenanthrene, 269  
 Oxidized drying oil acids, use in alkyd resins, 923, 924  
 Oxidized ester gum-linseed oil mixture in lacquers, 825  
 Oxidized hydrocarbons, esterification with alcohols, 911  
 Oxidized oil, in cold-molding composition, 1286  
 Oxidized paraffin, chlorinated, 1153  
 Oxidized rosin, uses, 775  
 Oxidized rubber resins, properties of, 1093  
 Oxidized substances, catalysts, in isoprene polymerization, 176  
 Oxidised wax, oxidation catalyst, 209  
 —, reaction with glycerol, 209

- Oxidising agents, action on chlorinated rubber, 1117**  
 —, — chloroprene rubber latex, 157, 158  
 —, — cumarone, 94  
 —, — films formed by acetylene polymers, 153, 154  
 —, — resinous substance from ethylene, 165  
 —, — catalysts, polymerisation of conjugated dienes, 178, 180  
 —, — reaction of cyclohexene with sulphur dioxide, 167  
 —, — purification of urea with, 567  
 —, — use in rubber-chlorination, 1108  
**Oxidising alkyds, 918-923, 925, 931-933, 972, 973, 976**  
 —, — anomaly in, 920  
 —, — compatibility with nitrocellulose, 921, 925  
 —, — driers, 976  
 —, — paint products, 972, 973  
 —, — patent history of, 921  
 —, — preparation of, in inert atmosphere, 922  
 —, — solubility of, 921, 923, 925, 931, 933  
 —, — use of rosin in, 931, 932, 933  
 —, — with other resins, 972  
**Oxidizing Rezyle in printing ink, 973**  
**Oximino group, in nitrated rubber, 1094**  
**Oxindole, oxidation, 744**  
**Oxonium compounds, from aromatic ethers and ketones, 560**  
**Oxycarbons, formation of, 1013**  
**Oxycellulose, filler, 458**  
**Oxycolophones, 730**  
**Oxygen, absorption by acetylene polymers, 143, 144, 145**  
 —, — cashew-shell oil, 1229  
 —, — cracked distillates, 230  
 —, — rubber, 1093  
 —, — vinylacetylene polymer, 150, 152  
 —, — accelerator, polymerization, vinyl acetate, 1020  
 —, — action on butadiene-homologue polymers, 199  
 —, — cumarone resin, 131  
 —, — cymene, 269  
 —, — durenene, 269  
 —, — indene, 103  
 —, — mesitylene, 269  
 —, — phenol-aldehyde resins, 335  
 —, — rubber, 1109  
 —, — triphenylmagnesium bromide, 1142  
 —, — xylene, 269  
 —, — catalyst, polymerization of conjugated dienes, 176, 179, 180, 183, 185, 186, 188  
 —, — — isoprene, 175, 176  
 —, — — olefins, 176  
 —, — thermal polymerization of acrylic acid, 1071  
 —, — reaction of cyclohexene and sulphur dioxide, 1173  
 —, — vinyl ester-aldehyde reaction, 1064, 1065  
 —, — effect on cuprene formation, 145  
 —, — polymerization of acetylene, 145  
 —, — polymerization of chloroprene, 155, 156  
 —, — polymerization of methylvinylidiodoacetylene, 161  
 —, — polymerization of oils, 1226  
 —, — rate of drying of acetylene polymers, 153  
 —, — reaction of sulphur dioxide with cyclohexene, 168  
 —, — in asphaltenes, 204  
 —, — inhibitor, of photopolymerization of acrylic acid, 1071  
 —, — in petroleum resins, 201, 202, 203  
 —, — purification of urea with, 567  
 —, — reaction with p-benzoquinone, 558  
 —, — carvone, 558  
 —, — 1,3-cyclohexadiene, 189  
 —, — cyclohexene, 167  
 —, — dehydrogenene dioxide, 560  
 —, —  $\beta$ -naphthoquinone, 558  
 —, — phenanthrenequinone, 558  
 —, — 1-phenyl-4-ethylcyclohexane-3,5-dione, 560  
 —, — piperitone, 558  
 —, — polycyclopentadiene, 188  
 —, — pulegone, 558  
 —, — removal of by alkaline pyrogallate, 494  
**Oxygenated phosphorous compounds, catalysts, rosin esterification, 795**  
**Oxygenated substances, in chloroprene polymerization, 153, 156**  
 —, — catalysts, isoprene polymerisation, 175  
 —, — styrene polymerization, 176  
**Oxygen catalysts, for polystyrenes, 238, 239, 240, 241**  
 —, — polymerizations, vinyl chloroacetate, 1022  
**Oxygen compressors, lubricant for, 996**  
**Oxygen content of cresol resins, 271**  
**Oxygen-convertible alkyd resins, nature of, 864, 918, 919, 920, 974**  
**Oxyturpentine, 730**  
**Oyster-shell lime, in hardening rosin, 772**  
**Osokerite, action of silica gel on, 203**  
 —, — aromatics from, 203  
 —, — asphalt from, 203  
 —, — chlorinated, properties of, 220  
 —, — constituent of insulating compound, 1091  
 —, — naphthenes from, 203  
 —, — olefins from, 203  
 —, — paraffins from, 203  
 —, — treatment of phenol-aldehyde moldings with, 284  
 —, — with castor oil, coatings from, 447  
 —, — with chlorinated tall oil, 756  
**Ozone, action on natural and synthetic rubber, 158, 1109**  
 —, — petroleum distillates, 210  
 —, — pine oil and ester gum, 781, 782, 806  
 —, — polycyclopentadiene, 188  
 —, — pyrrole, 740  
 —, — tung oil, 1217  
 —, — catalyst, phenol-formaldehyde reaction, 358  
 —, — polymerization of fatty oils, 1226  
 —, — — furylethylene, 522  
 —, — — olefins, 166  
 —, — — vinyl chloride, 1038, 1039  
 —, — polystyrenes, 238, 239, 240  
 —, — reaction with dimethylketene, 554  
 —, — olefins, 166  
**Ozone treatment of rosin, 774, 775**  
**Ozonide, of isoeugenol, 262**  
**Ozonides, catalysts, polymerization of methyl methacrylate, 1081**  
 —, — polystyrenes, 238, 239, 240  
 —, — decomposition of, 210, 262  
 —, — explosive character of, 166  
 —, — petroleum distillates, 210  
 —, — polymerization of, 166  
 —, — use of decomposition products of, 358  
**Ozonizer, decomposition of carbon monoxide by, 1013**  
**Ozonolysis, of isoeugenol, 262**  
 —, — of rubber, 1088, 1093

## P

- Packings, from phenol-aldehyde resins, 459, 485**  
**Paint, aluminum powder and glycerol phthalate resin in, 960**  
 —, — anti-corrosive, from sulphur-aniline resin, 1197  
 —, — bituminous, cumarone resin in, 130, 132, 133  
 —, — chemical resistant, with rubber, 1098  
 —, — cumarone resin, portland cement as pigment, 129  
 —, — drying Rezyle in, 956  
 —, — from coal-tar pitch, 275, 360  
 —, — from phenol-aldehyde resin, 365, 366, 368  
 —, — from tar-oil resin, 122  
 —, — from vinyl resins, 1048  
 —, — glycerol-esterified Manila copal varnish in, 817  
 —, — heat resistant silicon ester, 1236  
 —, — rust-preventing, alkyd resin in, 976  
 —, —, from sulphurised oil, 1208  
 —, — scrap rubber in, 778  
**Paint oil, from acid sludge, 217**  
**Paint pigments, from tar oils, 1203**  
**Paint products, oxidizing alkyd resins in, 972**  
 —, — use of Teglac in, 912  
**Paint remover, constituents of, 993**  
**Paints, acid resistant, chlorinated rubber in, 11**  
 —, — alkali resistant, chlorinated rubber in, 11  
 —, — colloidal nature of, 55, 56

- Paints, comparison of linseed oil with alkylid resin, 975
- , drying oil, use of methylol butyl urethane, 682
  - , drying oil acids in, properties of films, 974
  - , from acetylene-polymer drying oils, 154
  - , from alcohol resins, 1007
  - , from alkylid resins, 976
  - , from casein-modified phenol-formaldehyde resins, 417
  - , from chlorinated hydrocarbons, 220
  - , from chlororubber, 1108, 1111, 1116, 1117, 1118, 1119, 1120, 1121, 1122, 1123, 1124, 1125
  - , from cyclohexanol-modified phenol-formaldehyde resins, 417
  - , from diolefin-monoolefin co-polymerization, 190, 191
  - , from glue-modified phenol-formaldehyde resins, 417
  - , from modified urea-aldehyde resin, 685
  - , from oily polymers of 1,3-dienes, 185
  - , from petroleum asphalt reaction products, 274
  - , from polymerized hydrogenated divinylacetylene, 154
  - , from polyvinyl ester-acetals, 1066
  - , from reduced rubber, 1097
  - , from vinylacetylene, 150
  - , from vinyl ester-aldehyde resins, 1065
  - , iron protecting, from phenols, 273
  - , lead phenolate resin in, 273
  - , low-temperature tar oxidation products in, 273
  - , metallic, drying alkylid resins in, 979
  - , —, method of applying, 980
  - , metallic soaps in, 784, 788
  - , oxidized rubber in, 1093
  - , paulownia oil in, 817
  - , plasticity of, 35
  - , quick-drying, comparison with drying alkylid compositions, 973, 975
  - , Rezyls in, 973
  - , rosin in, 778, 779
  - , thixotropy of, 35
  - , use of alkylid resin emulsifications in, 948
  - , — crotonic acid in, 834
  - , — sorbic acid in, 834
  - , — squalene in, 199
- Paint vehicle, air-blown linseed oil, 1227
- , from turpentine, 781
- Palladium, catalyst, drying oil polymerization, 1228
- , —, for hydrogenation of esters, 807
  - , —, for oxidation of phenols, 271
  - , —, in hydrogenation of rosin, 769
  - , in preparation of naphthylidene derivatives, 1140
- Palladium hydride, reaction with carbon dioxide, 350
- Palmitate, of castor oil fatty acids, 1224
- Palmitic acid, esterification of phenol-alcohols with, 399
- , — wax alcohols with, 814, 815
  - , in driers, 787
  - , phenol-aldehyde resins fused with, 398
  - , separation of styrene analogues with, 253
  - , use in alkylid resins, 905, 907
- Pancreas extract, use of, as protective colloid, 181
- Paneling, fireproof, 657
- , surfaced with resin-coated sheet, 1245, 1246
  - , wall, of vinyl resins, 1333
- Papain, use of, as protective colloid, 181
- Paper, chlororubber-impregnated, 1127, 1128
- , coating with modified phenol resins, 398
  - , — sulphur, 1167
  - , — vinyl resins, 1047
  - , decorated, resin-coated, use, 1245, 1246
  - , dielectric strength, effect of, urea resins, 642
  - , Ellisols in impregnation of, 966
  - , filler for laminated products, 1274
  - , fireproofing, 1127
  - , from amine-aldehyde resins, 694
  - , gelatin-glycerol phthalate coating for, 965
  - , grease-resistant, preparation of, 968
  - , impregnated, grain visible, 1280
  - , —, polymerizing resin, 1245
  - , impregnation with alkylid resins, 897
  - , — chlorinated biphenyls, 1147
- Paper, impregnation with halogenated hydrocarbons, 1150
- , — modified phenol resins, 398
  - , — phenol-aldehyde resins, 643
  - , — sulphur, 1168
  - , — urea resins, 624, 625, 642, 643
  - , — vinyl resins, 1051
  - , incorporation with urea resins, 620
  - , laminated, alkylid resins as bonding agent for, 987
  - , —, uses of, 472, 473
  - , mechanical strength, effect of urea resin, 642
  - , parchmentized, impregnation, 1245
  - , resin impregnated, uses of, 472, 1246, 1283
  - , sheets, method of applying resinous binder, 1281
  - , sizing, cumarone resin in, 139
  - , sodium bisulphate impregnated, use, 1328
  - , translucent, alkylid resin in preparation of, 969
  - , transparent, castor-oil impregnated, 1245
  - , —, use of resins, 1245
  - , use, decoration of moldings, 1333
  - , —, laminated insulation, 1247
  - , varnished, breakdown voltage in, 1348
  - , waterproofing of, 180, 721, 1168
  - , writing, treatment, urea resins, 640
- Paper-asbestos mixture, use, filler, 1250
- Paper coating composition, preparation of, 968
- Paper coatings, ester gum in, 838
- Paper decorations, permanence, effect of urea resins, 642
- Paper fiber, as filler for phenol-aldehyde resins, 365, 460, 461
- Paper filled materials, testing of, 1342
- Paper impregnated, from rubber, 1097
- Paper insulating sheets, phenol-aldehyde resin binder, 452
- Paper-like materials, amine-aldehyde resins, 692
- Paper linings, use of, polymerization apparatus, 179
- Paper pulp, decolorizing, 1250
- , incorporation with phenol resin, 457, 460, 461
  - , — urea resins, 625, 626
- Paper pulp-alkylid resin compositions, fillers for, 987
- Paper size, from latex, 1094
- Paper-sizing machine, use of, 334
- Papier-mâché impregnated, acid-proofing, 1205
- Paracumarone, from cumarone, 96
- Paracumarone sludge, with cumarone resin, 139
- Paracumarone soap, 112, 113
- Paraffin, chlorination, 219, 220, 1154, 1220
- , constituent of polishing wax, 993
  - , effect on chlororubber oil varnish, 1124
  - , in chlorobiphenyl compounds, 1147
  - , oxidation of, 209, 211
  - , oxidized, butyl ester, use as plasticizer, 685
  - , reaction with alginic acid, 1254
  - , softener for rubber products, 1098
  - , use as mold-lubricant, 1327
  - , use in coal-tar-pitch composition, 360
  - , — flooring compositions, 983
  - , use of, 332
  - , use with chlororubber, 1123
  - , — nitrocellulose, 1243
- Paraffin hydrocarbons, in cuprene tar, 146
- , oxidation of, 911
- Paraffin oil, resinified by chlorine, 211
- , in preparation of pitch from wash-oil, 122
- Paraffin oil solution, polymerization of acrylic acid derivatives with vinyl compounds in, 1076
- Paraffin paper, ester gum solution as coating for, 837
- Paraffins, from masout, 203
- , from osocerite, 203
  - , long chained, formation of, 35
  - , oxidation of, 217
  - , specific viscosity of, 73
  - , sulphonation of, 217
  - , use in rubber compositions, 435
- Paraffin wax, combination with plastic sulphur, 1163
- , in chewing gum, 823
  - , in coating composition for paper, 968
  - , in gutta-percha substitute, 1204
  - , in preparation of flooring composition, 984

- Paraffin wax, treatment of phenol-aldehyde moldings with, 284
- Paraffined paper, adhesive for, 1126
- Paraform, condensation with carbolic acid, 345
- , — pyrogallol, 372
- , — thiourea, 654
- , — from formaldehyde, 512
- , — hardening phenol-sulphur resins with, 1138
- , — reaction with cashew-shell oil, 1230
- , — o- and p-saligenins, 298
- , — vinyl compounds, 1065
- , — use in phenol-aldehyde reaction, 350, 367, 415
- , — with tar acid-aldehyde resin, 369
- Paraformaldehyde, condensation with ammonium thiocyanate, 660
- , — aniline, 691, 695
- , — coal-tar oils, 363
- , — dibenzylamine, 707
- , — diethylamine, 707
- , — 2-ethoxynaphthalene-3-carboxylic acid, 374
- , — 1,3,4-hydroxytoluic acid, 374
- , — p-nitrochlorobenzene, 726
- , — phenol, 1031
- , — resorcinol, 371, 373
- , — tetrahydronaphthalene, 265
- , — thiourea, 645
- , — urea, 604, 612, 615, 616, 617, 645
- , — elasticity promotion by urea resins, 593
- , — hardening agent, amine resins, 732, 1135
- , —, — for cashew-shell oil, 1232
- , —, — for phenol resins, 372, 373, 380, 393, 443
- , — polymerization of, 516
- , — reaction with cyclohexanol, 377
- , — dihydroxydiphenylethane, 382
- , — diphenylmethane, 297
- , — phenols, 416
- , — toluenesulphonamides, 712
- , — xylene and tung oil, 403
- , — xylenols, 407, 408
- , — use of, 326, 400
- , —, — in modified alkyd resins, 936
- , —, — in phenol-aldehyde resins, 316, 318
- , —, — removing excess phenols from phenol-aldehyde resins, 365
- Paraformaldehyde-cresylic acid resin, ejected hot from press, 365
- Paraformaldehyde-tetrahydronaphthalene reaction, catalyst for, 265
- Paralindene, from indene, 101
- , — hydrogenation of, 119
- , — molecular weight of, 101
- Paraldehyde, as hardening agent, 385, 1138
- , — bromination of, 506
- , — condensation with cresols, 364, 365
- , — lactic acid, 1004
- , —  $\beta$ -naphthylamine, 689
- , — resorcinol and tung oil monoglyceride, 405
- , — tar oil, 362
- , — formation of, 489, 494
- , — in stencil sheets, 962
- , — preparation of, 489
- , — reaction with phenol, 380, 381, 382
- , — phenols and cyclohexanone, 390
- , — vinyl compounds, 1064
- , — use in phenol-aldehyde reaction, 418
- Paraldehyde-cresol resin, binder for cold-molding composition, 1238
- , — solubility of, 364
- Paraldehyde-salicylic acid resin, use in photographic plates, 375
- Paraldol, from acetal, 498
- Parallel planes, in cubic lattice, 78
- Paraplex RG-2, incompatible, chlororubber, 1119
- Parohment, imitation, impregnated paper, 1245
- Parohmentised fiber, impregnating with phenol-aldehyde resins, 484
- Parohmentised paper, impregnation with resin, 473
- Parohment-like paper, use of alkyd resins in making, 969
- Parohment paper, treatment with urea resins, 643
- Paris white, use with chlorinated rubber, 1108
- Particle size, influence on plasticity, 33, 33
- Pasteboard, decorating, use of chlororubber, 1128
- Pastes, polyethylene oxide, 993
- Paulownia oil, in coatings, 817
- , — properties of, 818
- , — source of, 818
- Paving materials, metallic soaps in, 791
- Peanut hulls, digestion with phenols, 748
- Peanut oil, plasticizer, chlororubber, 1126
- , —, — vinyl resins, 1050
- Pearl dust, incorporation with urea resins, 641
- Pearl essence, use of metallic alkyl phthalates in, 951
- Pearls, artificial, from synthetic resins, 1250
- Peat, addition to a phenol-aldehyde product, 365
- , — condensing agent, 355
- , — filler, sulphur castings, 1166
- , —, — incorporation with urea resins, 623
- , — resins from, 749
- , — Russian, resins from, 274
- , — saccharification, 749
- , — use, with synthetic resins, 1250
- Peat meal, use in linoleum, 198
- Peat residues, treatment with ethylene dichloride, 749
- Peat-tar phenols, sulphonated, reaction with formaldehyde, 419
- , —, — tanning agents from, 419
- Pectins, use in chloroprene rubber latex, 157
- Pectose-aldehyde-ketone condensation, 763
- Pectous material, utilization, 762, 763
- Pencil tests, for hardness of varnish, 1371, 1372
- Pendulum, swinging beam, hardness tests with, 1371, 1372
- Penetration, water, tests for, 1343
- 1,2,2,3,4-Pentachlorobutane, dechlorination of, 160
- , — formation of, 160
- Pentachloroethane, plasticizer, chlororubber, 1123
- Pentachlorophenol, softening agent, phenol-aldehyde resins, 423
- Pentadecatetrone, formula of, 1089
- 2-n-Pentadecylglyoxalidine, use in emulsification of 1,3-dienes, 189
- Pentaerythritol, condensation with ether-acids, 902
- , — maleic acid, 901
- , — phthalic anhydride, 901
- , — succinic acid, 901
- , — from formaldehyde and acetaldehyde, 900
- , — reaction with acetic acid, 901
- , — dicarboxyethers, 901, 902
- , — 9,10-dihydroxystearic acid, 901
- , — ethyl chloride, 901
- , — ethylene oxide, 899
- , — propylene oxide, 899
- , — tetrahydrobenzene oxide, 899
- , — rosin esters with, 796
- , — use in alkyd resins, 914, 924, 931, 949
- , — use in preparation of alkyd resins, 969
- Pentaerythritol-phthalic anhydride composition, 914
- Pentaerythritol tetra-acetate, preparation, 901
- Pentaglycerol, use in preparation of alkyd resin, 969
- Pentaglycerol hepta-acetate, preparation of, 995
- Pentaisobutylene, from isobutylene, 166
- Pentamethylbenzene, action of sulphuric acid, 266
- , — tars from, 266
- Pentamethylene carbonate, dimer of, 870
- Pentamethylenediaminedisulphine, coating and impregnant, 1180
- , — plasticizer, 624, 1180
- , — preparation, 1180
- , — resistance to alkalies, 1180
- , — vulcanisation accelerator, 1180
- Pentamethylene tetrasulphide, preparation, 1170
- Pentane, diluent in cyclohexene polymerisation, 167
- Pentene, from hydorrubber, 1096
- 2-Pentene, reaction with isoprene, 190
- 2-Pentene-isoprene reaction, aluminium chloride catalyst in, 190
- Pentenes, from sodium rubber, 1089
- , — polymerisation of, 166
- Penthasoline derivatives, halogenated, 1158
- Pentosans, furfural from, 517
- Peptides, synthesis of, 66

- Peracetic acid, oxidation of furan with, 519  
 —, preparation of, 1093  
 —, reaction with rubber, 1093  
 Peracids, catalysts, from polystyrenes, 238, 239, 240  
 —, —, in isoprene polymerisation, 176  
 —, —, in styrene polymerisation, 176  
 Perbenzoic acid, action on asphaltenes, 203  
 —, —, heptenes, 1254  
 —, —, indene, 103  
 —, —, petroleum resins, 203  
 —, effect on oxidation of styrene, 239  
 —, polymerisation of styrene, 239  
 Perborates, catalysts, polymerisation of 1,3-dienes, 180  
 —, —, —, vinyl acetate, 1022, 1023  
 —, —, vinyl-ester polymerisation, 1022, 1023, 1057  
 —, purification of resins with, 336  
 Perchloric acid, in varnish, prevention of yellowing, 1378  
 Perforated sheets, preparation, 1334  
 Perfumes, by diene synthesis, 160  
 Perilla oil, modifier, alkyl resins, 977  
 —, stand oil from, 1226  
 Permanganate, making rubber non-tacky with, 1094  
 Permeability of chloroprene rubber to gases, 158  
 —, of ester gum coatings to moisture, 818  
 —, of laminated materials, 1344  
 —, of varnishes, tests for, 1875, 1876, 1877  
 Permutoid reactions in cellulose, 64  
 Permtrosoketocineole, reaction with sulphuric acid, 727  
 Peronospora, fungus, destruction of, 1186  
 Peroxide, from cyclohexene, 167  
 —, oxidising of cottonseed oil foots with, 1233  
 Peroxides, accelerators, polymerisation of vinyl acetate, 1020  
 —, by oxidation of gasoline, 223, 224  
 —, catalyst, aldehyde polymerisation, 505  
 —, —, for polystyrenes, 238, 239, 240  
 —, —, for styrene polymerisation, 176  
 —, —, isoprene polymerisation, 176  
 —, polymerization of butadiene homologues, 175  
 —, effect on chloroprene polymerization, 155, 156  
 —, —, polymerisation of butadienol esters, 152  
 —, from ketenes, 554  
 —, in oxidised rubber, 1093  
 —, intermediates, gum-formation, 223  
 Per-salts, catalysts, isoprene polymerisation, 176  
 Persulphates, catalysts, vinyl-ester polymerisation, 1057  
 —, purification of resins with, 336  
 —, use, oxidation, urea-phenol-aldehyde resins, 675  
 Peru balsam, combination with polyvinyl chloride, 1038  
 Peru-balsam type resin, preparation of, 1254  
 Perylene, reaction with maleic anhydride, 841  
 Petrolatum wax, with ester gum in waterproofing compositions, 828  
 Petroleum, acidic resins from, 201  
 —, asphalt and pine tar, oxidation of, 230  
 —, asphaltenes from, 201, 202, 203, 204  
 —, asphaltic acids from, 203, 205  
 —, asphaltis from, 201  
 —, carbones from, 201, 202  
 —, carboids from, 202  
 —, chlorination of, 1154, 1155  
 —, cracked, polystyrene from, 254  
 —, light, solvent for polymers of 1,3-dienes, 182  
 —, naphthenic acids from, 203, 205, 206  
 —, neutral resins from, 201, 203  
 —, oxidation of, 208-211  
 —, petrosene from, 203  
 —, raw material for resin production, 9  
 —, refined, action on films of acetylene polymers, 163  
 —, rubber-like material from, 191  
 —, source of resins, 201  
 —, use in preparation of pitch from wash-oil, 123  
 Petroleum asphalt, action of sulphuric acid on, 274  
 —, nitration of, 202  
 Petroleum distillates, diluents in cumarone polymerisation, 116  
 —, effect on chloroprene rubber, 158, 159  
 —, reaction with sulphur chloride, 1203  
 —, solvents for Teglaes, 956  
 Petroleum ether, extraction of oxidized linseed oil with, 1226  
 —, precipitation of phenol-aldehyde resins, 362  
 —, purification of rosin soap, 753  
 Petroleum fractions, butadiene from, 176  
 Petroleum hydrocarbons, action of sulphuric acid on, 217  
 —, aldehydes by oxidation of, 671  
 —, chlorination, 219, 220, 221  
 —, diacetylene from, 162  
 —, electropyrolysis of, 162  
 Petroleum jelly, in insulating compound, 1091  
 —, softener for balata and gutta-percha, 1091  
 Petroleum naphtha, solvent for hydrogenation of esters, 807  
 —, use in precipitation of phenol-aldehyde resins, 364  
 Petroleum oil, action of fermented hay on, 230  
 —, —, fermented molasses on, 230  
 —, nitration of, 728, 729  
 —, nitro resins from, 728  
 Petroleum residues, action of sulphur on, 216  
 —, neutralisation, 217  
 —, oxidation of, 217  
 —, treatment with sulphur chloride or sulphur, 1204  
 Petroleum resins, action of heat, 202  
 —, —, sulphuric acid on, 202, 203  
 —, nitration of, 202  
 —, oxygen in, 201, 202  
 —, reaction with formaldehyde, 202, 203  
 —, —, perbenzoic acid, 203  
 —, sizing agents, 204  
 —, solvents for, 202  
 —, sulphur, in, 201, 202  
 Petroleum tar, action of aluminum chloride, 215  
 —, chlorination of, 1157  
 —, reaction with iron, 217  
 —, resins from, 215  
 Petroleum-tolerance of Rezyls, 973  
 Petroseene, dyes from, 203  
 Petroseene, from petroleum, 203  
 Pfund glossmeter, 1356  
 Pharmaceutical, tannin-modified urra-aldehyde resin, 678  
 Pharmaceuticals, by diene synthesis, 160  
 —, from cumarone-resin by-products, 112  
 Phellandrene, catalyst, styrene polymerization, 240  
 —, reaction with acrolein, 843, 844  
 Phenacyl bromide, reaction with  $\alpha$ -aminopyridine, 738  
 —, —, phenyl pyrimidasole, 738  
 $\alpha,\alpha'$ -bis-Phenacetylmethylamine, from aceto-phenone, 557  
 Phenanthrene, action of canal rays on, 269  
 —, —, hydrogen peroxide on, 269  
 —, —, oxides of nitrogen on, 269  
 —, —, sodium and amyl alcohol on, 268  
 —, autocondensation, 266  
 —, —, aluminum chloride as catalyst, 266  
 —, chlorination of, 1137  
 —, condensation with aromatic hydrocarbons, 266  
 —, —, olefins, 194  
 —, diphenic acid from, 269  
 —, hydrogenation of, 268  
 —, quinone from, 269  
 —, reaction with benzal chloride, 1134  
 —, resin from, 269  
 —, solvent, polyvinyl chloride, 1088  
 —, tars from, 724  
 —, action on maleic anhydride, 841  
 Phenanthrene-formaldehyde resins, properties of, 364  
 Phenanthrenequinone, reaction with oxygen, 558  
 Phenetole, action of formaldehyde on, 265  
 Phenol, action of air on, 370, 371  
 —, action of ferric chloride on, 370  
 —, action of lead oxide on, 370, 373  
 —, action on cellulose, 745, 750  
 —, —, corn cobs, 745

- Phenol, action on cotton, 748
- , — grass, 749
  - , — rubber, 1104
  - , — wood, 747, 748, 749, 750
  - , capable of thermohardening, 826
  - , catalysts for air oxidation of, 271
  - , — phenol-formaldehyde-reaction, 353, 355
  - , comparison with cresols in reactions with formaldehyde, 304
  - , condensation with sulphite liquor, 754
  - , conversion of sols by, 596
  - , decomposition of, 272
  - , diphenylol-1,1-cyclohexane from, 560
  - , effect on amorphous ethylene sulphide, 1169
  - , electrolysis of, 272
  - , electrolytic oxidation of, 271
  - , esterification of abietic acid with, 397
  - , — copals with, 809, 810, 811
  - , — rosin with, 799, 800, 801
  - , exoos, use in phenol resins, 328, 488
  - , free, effect on phenol-aldehyde resins, 249, 335
  - , from benzenesulphonic acid, 360
  - , from by-product coke ovens, 360
  - , from catechol, 270
  - , from chlorination of benzene, 360
  - , from cumarone resin, 95
  - , from diphenyl ether, 270
  - , from phenyl vinyl ether, 1009
  - , glyceride oils modified with, 1227
  - , gum inhibitor, 224
  - , hydroxyether from, 1009
  - , importation of, 359
  - , indene from, 90
  - , in oxidation of rosin, 774
  - , in rosin purification, 768
  - , in wood tar, 731
  - , methylene ratio, of phenol-formaldehyde resins, 321
  - , modifier, chlororubber paint, 1126
  - , —, dicyanodiamide-formaldehyde resin, 680
  - , —, polyvinyl acetals, 1064
  - , oxidation of, 271, 272
  - , percentage resin yield by weight of, 322, 323
  - , phenol alcohol from, 332
  - , positions of attack in, 292
  - , production of, 359, 360
  - , purification of, 336

  - , clear, preparation of, 468
  - , cylinders from, 464
  - , effect of light, 1267, 1268
  - , effect of over-curing of resin, 465
  - , glass facings in, 467
  - , metal reinforcements for, 465, 466
  - , hollow balls from, 464
  - , phenol-resin scrap, filler, 462, 463
  - , treatment with wax, 284
- Phenol-aldehyde reaction, acetanilide, catalyst, 348
- , acetic acid catalyst, 429, 430
  - , acetyl chloride, catalyst, 357
  - , acid catalysts for, 348-351, 439, 445
  - , alkyl resins, catalysts, 350, 351
  - , aluminum chloride, catalyst, 356
  - , aluminum hydroxide, catalyst, 345
  - , aminophenols, catalysts for, 346, 347
  - , ammonia, catalyst, 309, 318, 344-346, 348, 353, 357, 363-365, 370, 417, 430, 432, 434, 439
  - , ammonium bicarbonate, catalyst, 353
  - , ammonium carbonate, catalyst, 345
  - , ammonium chloride, catalyst, 357, 363, 364
  - , ammonium sulphate catalyst, 363
  - , ammonium thiocyanate, catalyst, 353
  - , aniline, catalyst, 345, 346, 347
  - , baryta water, catalyst, 343
  - , basic catalysts for, 344-348, 368, 445
  - , benzenesulphonic acid, catalyst, 430
  - , benzylamine catalyst, 363, 365
  - , benzyl chloride, catalyst, 357
  - , boric acid, catalyst, 349
  - , boron fluoride, catalyst, 400
  - , butylamine, catalyst, 347
  - , calcium bromide, catalyst, 357
  - , calcium carbonate, catalyst, 354
- Phenol-aldehyde reaction, calcium chloride, catalyst, 356
- , calcium cresolate, catalyst, 355
  - , carboic acid, catalyst, 353, 355
  - , carbon dioxide, catalyst, 349, 350
  - , carbon disulphide, catalyst, 345, 346
  - , caustic potash, catalyst, 343, 675
  - , caustic soda, catalyst, 343, 344, 346, 349, 352, 353, 415
  - , chlorine, catalyst, 357, 358
  - , chloroaminoaldehydes, catalysts, 348
  - , copper carbonate, catalyst, 356
  - , cupric hydroxide, catalyst, 345
  - , cyclohexylamine, catalyst, 347
  - , dicyanodiamide, catalyst, 346
  - , dicyclohexylamine, catalyst, 347
  - , diethanolamine, catalyst, 347
  - , dihydrogen phosphates, catalysts, 353
  - , dimethylaniline catalyst, 347
  - , dithiocarbamates, catalysts for, 348
  - , effect of ammonia in, 428
  - , — hydrocarbons on, 363
  - , — hydrogen ion concentration in, 352, 353, 439, 440
  - , — hydroxyl groups on velocity, 371
  - , — resorcinol, 373
  - , fatty acids, catalysts, 350, 351, 357
  - , ferric chloride, catalyst, 356
  - , ferrous sulphate catalyst, 363
  - , formic acid catalyst, 416
  - , furfural, catalyst, 348
  - , glycolic acid, catalyst, 354
  - , guanidine carbonate, catalyst, 345
  - , halogens, catalysts, 357, 358
  - , hexamethylenetetramine derivatives, catalysts, 346
  - , hydrazine, catalyst, 346
  - , hydrobenzamide, catalyst, 348
  - , hydrochloric acid, catalyst, 296, 343, 346, 348, 349, 351, 352, 353, 355, 366-369, 397, 398, 426, 429, 430
  - , hydrogen peroxide catalyst, 416
  - , hydrogen sulphide, catalyst, 345, 346
  - , hydroxydiphenylamine, catalyst, 346, 347
  - , hydroxylamine, catalyst, 346
  - , hydroxynaphthylmethylsulphonic acid from, 352
  - , hydroxyquinoline, catalyst, 346, 347
  - , indophenol, catalyst, 347
  - , latex as solvent, 435
  - , lead acetate, catalyst, 357, 369
  - , lead oxide, catalyst for, 343, 403
  - , lime, catalyst, 364, 425, 438
  - , magnesium oxide, catalyst, 370
  - , malic acid, catalyst, 354
  - , manganese oxide, catalyst, 408
  - , methylaminophenols, catalysts, 346, 347
  - , milk of lime, catalyst, 343
  - , monoethanolamine, catalyst, 347
  - , naphthalene- $\alpha$ -sulphonic acid, catalyst, 352
  - , organic acid catalysts, 349
  - , oxalic acid, catalyst, 369, 429, 431
  - , ozone, catalyst, 358
  - , p-phenolsulphonic acid, catalyst, 352
  - , phenyl-endekasilgenosilgenin from, 329
  - , phosphoric acid, catalyst, 349, 353, 430
  - , phosphorus pentachloride, catalyst, 357
  - , pinene ozonide, catalyst, 358
  - , piperidine dithiocarbamate, catalyst, 345
  - , potassium bromide, catalyst, 357
  - , potassium carbonate, catalyst, 343, 415
  - , potassium cyanide, catalyst, 343, 345
  - , potassium ferrocyanide, catalyst, 356
  - , potassium hydroxide catalyst, 343, 346, 363, 423, 439, 675
  - , potassium permanganate, catalyst, 348
  - , pyridine, catalyst, 345, 362
  - , quicklime, catalyst, 345
  - , removal of water, 363, 369
  - , salts, catalysts, 352-357
  - , salts of hydroxy acids, catalysts, 354
  - , sandarac ozonide, catalyst, 358
  - , slaked lime, catalyst, 346
  - , soaps, catalysts, 355
  - , sodium acetate, catalyst, 343, 415
  - , sodium bromide, catalyst, 357

- Phenol-aldehyde, sodium carbonate catalyst, 343, 349, 352-354, 360, 417, 420, 439, 673
- , sodium cresylate, catalyst, 352
  - , sodium cyanide, catalyst, 353, 357
  - , sodium hydroxide, catalyst, 323, 324, 363, 364, 367, 368, 423
  - , sodium nitrate, catalyst, 357, 358
  - , sodium peroxide, catalyst, 416
  - , sodium phenolate, catalyst, 420
  - , sodium salicylate, catalyst, 353, 354, 417
  - , sodium sulphide, catalyst, 354
  - , sodium sulphite, catalyst, 353, 355
  - , sodium thiosulphate, catalyst, 354-356
  - , sodium tungstate, catalyst, 354
  - , solid aldehydes for, 316
  - , stannic chloride, catalyst, 356
  - , strontium hydroxide, catalyst, 345
  - , succinic acid, catalyst, 360
  - , sulphonated naphtha, catalyst, 351
  - , sulphonic acid salts, catalysts, 351, 352
  - , sulphur chloride, catalyst, 357
  - , sulphur dioxide, catalyst, 349, 350
  - , sulphuric acid, catalyst, 331, 343, 345, 349, 350, 357, 361, 363, 366, 369, 420, 430, 437-439, 674
  - , sulphuryl chloride, catalyst, 357
  - , temperature of, 363
  - , titanium salts, catalysts, 354
  - , translucent resins from, 467
  - , trisodium phosphate, catalyst, 354
  - , urea, catalyst, 345
  - , use of acetaldehyde, 418, 419
    - , alcohol, 369
    - , alkaline peat solution, 365
    - , coal-tar oils, 354, 355
    - , cresol, 424, 430
    - , dicyanodiamide, 675, 676
    - , enameled vessels, 319
    - , formaldehyde gas, 355
    - , fusel oil, 283, 284
    - , methylal, 430
    - , mineral oils, 354, 355
    - , mixed aldehydes, 363
    - , paraformaldehyde, 316
    - , paraldehyde, 418
    - , pressure, 361, 365
    - , pyroligneous acid, 761
    - , salt mixture, 424
    - , sludge sulpho-acids, 415
    - , tar-oil diluents in, 362
    - , tinned-iron vessels, 319
  - , velocity of, compared to Reimer-Tiemann reaction, 366
  - , zinc acetate, catalyst, 360, 400
  - , zinc chloride, catalyst, 352, 356
  - , zinc dust, catalyst, 343
  - , zirconium chloride, catalyst, 356
- Phenol-aldehyde resins, acetanilide-modified, 429
- , acetone-modified, 428
  - , acetophenone-modified, 431
  - , acetylated derivatives of, 320
  - , acid-anhydride-modified, 439
  - , acid numbers for, 397, 400
  - , acid-resistance, 352, 353
  - , acid-resistant coatings with, 450
  - , acid-resistant filter cloth with, 430
  - , acylated, color-stability of, 422
  - , effect of formaldehyde, 426
  - , acylation with wax acids, 426
  - , adherence to metal, 480
  - , adherence to mica, 982
  - , adhesives from, 479-481, 486
  - , alkaline solutions of, 319
  - , alkyl resins with, 428, 430, 445, 447, 476, 496
  - , alkyl celluloses with, 494
  - , aluminum oxide, filler, 460
  - , aluminum stearate-modified, 424
  - , analytical scheme, 1287
  - , anhydroformaldehyde-aniline-modified, 423
  - , aniline black with, 357
  - , anisole-modified, 431
  - , anti-fouling paints from, 451
  - , artificial pearls from, 484
  - , asbestos, filler, 453, 459
  - , asbestos-filled, molding of, 1332, 1333
  - , coatings from, 453
  - , barium soap-modified, 433
  - , barium sulphate with, 477
  - , basic oxide-modified, 438
  - , benzoic acid-modified, 424
  - , benzyl acetate, modifier, 399, 400
  - , binders, for abrasives, 460
    - , electrical insulation, 461
    - , imitation wood veneer, 433
    - , paper insulating sheets, 452
    - , plywood, 477, 478
    - , schist bearings, 461
    - , waterproof matches, 460
  - , binders from, 329
  - , bleaching of, 339, 429
  - , blistering of, 1328
  - , butyl phthalate, modifier, 399, 400
  - , butyl stearate with, 424
  - , calcium carbonate-modified, 436
  - , calcium oxide-modified, 436, 437
  - , camphene-modified, 433
  - , camphor-modified, 423, 430, 441
  - , carbohydrate-modified, 430
  - , carbonization of, 463, 982
  - , carbon paper from, 452
  - , carborundum, filler, 460
  - , carboxylated, preparation, 427-429
  - , casein-modified, 430
  - , casting of, 286, 287, 323, 369, 419, 1313
  - , castor oil-modified, 406, 439
  - , celluloid with, 480
  - , cellulose esters with, 430, 432-434, 446, 447
  - , cellulose-modified, 433, 434
  - , cement, filler, 461
    - , impregnated with, 482
  - , cements from, 479
  - , charcoal, filler, 461
  - , chemical reactions involved, 291
  - , chemical resistance of, 365, 448
  - , chloronaphthalene solvent for, 443, 444
  - , chloronaphthalene waxes with, 486
  - , chromium oxide, filler, 460
  - , clarifying, 423, 429
  - , coatings, for aircraft, 448
    - , candles, 965
    - , cellulose-ester films, 452, 476
    - , concrete, 451
    - , ebonite panels, 451
    - , electric condensers, 450
    - , electric-light bulbs, 453
    - , food-containers, 448
    - , hydrochloric acid containers, 450
    - , laminated sheets, 987
    - , leather, 453
    - , luminescent paint containers, 450
    - , metals, 443, 449
    - , rubber, 453
    - , sulphur chloride containers, 450
    - , wood, 450, 451
  - , coatings from, 235, 329
  - , coke, filler, 461
  - , cold-molding of, 437, 470, 1287-1289
  - , colloidion with, 447
  - , colloidal dispersion of, 325, 326
  - , colophony, modifier, 397
  - , coloring of, 237, 442, 443
  - , color permanence of, 335
  - , color reactions with metallic chlorides, 310
  - , comparison with phenol-lignite resins, 374
    - , urea resins, 11
  - , compatibility with cellulose esters, 445
    - , other binders, 484
  - , condensing agents for, 289, 290
  - , constituents, 1257
  - , controlling agents for, 329
  - , conversion in "bakeliser," 364, 454
  - , conversion of insoluble to soluble, 340, 341
  - , conversion with sodium hydroxide, 341
  - , copals, modifiers, 396, 397
  - , copiaba resin, modifier, 398
  - , corundum, filler, 460
  - , grease-proof fabrics with, 452
  - , curing of, 366, 367, 454, 455, 1320
  - , cylinders from, 470
  - , defects of, 934

- Phenol-aldehyde resins, dehydration of, 339, 340, 353
- , dental plates from, 464, 465
  - , diacetin-modified, 428, 429
  - , dibutyl phthalate, plasticiser, 445
  - , p-dichlorobenzene-modified, 433
  - , dicyanodiamide-modified, 680, 681
  - , diethyl phthalate-modified, 430
  - , dispersion in colloid mill, 445
  - , drying oil-modified, 433
  - , dry processes, 316
  - , dyes for, 320, 453
  - , dyestuff-modified, 442
  - , ebonite substitute from, 283, 284
  - , effect of air on, 335
  - , — casting on transparency, 467
  - , — condensing agents, 285, 335, 448
  - , — fish scales in, 320
  - , — free phenol on, 335
  - , — heat on, 285, 369, 424
  - , — hexamethylenetetramine, 441
  - , — lead salts, 354
  - , — light on, 324, 335
  - , — mica in, 320
  - , — pressure, 285, 346
  - , — resin ester in, 397
  - , — sulphur monochloride, 441
  - , — waxes in, 320
  - , electrical apparatus from, 466
  - , electrically insulating thread from, 484
  - , electrodeposition of, 470
  - , emery, filler, 460
  - , emulsions of, 325, 326, 441, 457, 1334
  - , ester gum with, 799
  - , ester-modified, 430-433
  - , ether-alcohol-modified, 429
  - , expansion properties of, 438
  - , extraction of, 361
  - , faience-modified, 441
  - , fatty-acid salt-modified, 437
  - , ferrio oxide, filler, 460
  - , fiber tubes waterproofed with, 452
  - , fillers for, 317, 463
  - , flameproof cloth with, 452
  - , from saligenin, 479
  - , fusible, formation of, 318, 319
  - , fusion with colophony, 397
  - , — organic acids, 398
  - , gelation of, 337
  - , glass-substitute from, 453
  - , glue with, 429, 435, 486
  - , glycerol-modified, 423, 429, 429
  - , glyceryl ester-modified, 428-430
  - , glycol monoesters, modifiers, 399
  - , glycol monoethers, modifiers, 399
  - , graphite, filler, 450, 459, 460
  - , hardened with catechol tannin, 441
  - , — formaldehyde compound, 330
  - , — furfural-aniline condensate, 535
  - , — hexamethylenetetramine, 316, 318, 319, 423, 424, 431, 437, 438, 443
  - , — hydrobenzamide, 431
  - , — paraformaldehyde, 443
  - , — trioxymethylene, 423
  - , hardening of, 344, 345
  - , heat-hardening of, 337, 353, 362-364
  - , heat marks on, 1230
  - , hexamethylenetetramine flux for, 318
  - , history of industry, 359, 360
  - , hydraulic presses for molding, 463
  - , hydrogenation of, 419
  - , identification, 1257
  - , impact molding material from, 462
  - , impregnants from, 362, 365, 481-483
  - , — tests for non-volatile matter in, 1263, 1364
  - , — time of curing, 1262
  - , impregnation of asbestos with, 472, 483
  - , — canvas with, 471
  - , — electric coils with, 440, 452
  - , — fabrics with, 452
  - , — leather with, 475
  - , — paper with, 451, 452, 477
  - , — wood veneer with, 477
  - , incandescent-lamp filaments from, 285
  - , incorporation with aldehyde-amine resins, 711
  - , — cumarone resin, 121
  - Phenol-aldehyde resins, incorporation with fillers, 455-458, 463
    - , — furfural-aniline resin, 702
    - , — polyvinyl resins, 1027
    - , — sulphur, 1168
    - , induction-coil cores from, 460
    - , industrial by-products with, 487
    - , infusible, molding of, 464
    - , injection molding of, 1324, 1325
    - , insoluble, varnishes from, 445
    - , insulating varnishes from, 450
    - , iodoform-modified, 431
    - , iron, filler, 459, 460
    - , iron-oxide modified, 437, 438
    - , ivory-like, 429
    - , Japanese lac, modifier, 398, 399
    - , laquers from, 400
    - , laminated board from, 338, 362
    - , laminated materials from, 452, 470-481
    - , lampblack with, 287
    - , lanolin, lubricant, 455
    - , lead, filler, 459
    - , leather substitute from, 435, 486
    - , light-sensitive, 431, 453
    - , light-stability of, 661
    - , limed, hot-molding, 438
    - , linoleum from, 485
    - , long-fiber fillers with, 461, 462
    - , magnesium carbonate-modified, 426-438
    - , magnesium oxide-modified, 436-438
    - , manganese dioxide, filler, 460
    - , Manila copal, modifier, 393
    - , mechanical features of molds for, 463
    - , metal soaps in, 789
    - , methods of fabric impregnation with, 471, 474
    - , methyl cellulose ethers with, 446
    - , mica, filler, 459
    - , milling of molding powder, 455
    - , modified, uses of, 419, 431, 441, 442
    - , modified with cracked-petroleum polymers, 425
    - , — drying oil and rosin, 404
    - , — sulphonated naphtha, 419
    - , modifiers, for urea-aldehyde resins, 661
    - , modifying agents for, 317, 371
    - , molded articles from, 253, 314, 1332
    - , molding of, 362, 363, 365, 369, 370, 463
    - , molding powder from, 344, 345, 398
    - , molding pressures for, 328, 1319
    - , molding temperatures for, 1319, 1320
    - , molding time for, 317
    - , montan wax-modified, 438
    - , mordant from, 340
    - , naphthalene-modified, 440
    - , natural resins, modifiers, 396-402, 408, 684
    - , nitrobenzene-modified, 440
    - , nitrocellulose with, 446, 447
    - , non-sticking, 321
    - , oil-modified, 402-406
    - , — rubber cement from, 1104
    - , oil-resistant packing with, 435
    - , oil-soluble, 368, 412, 442, 520
    - , oil-treated Resyls with, 973
    - , one-stage wet process, 322-326
    - , opacity to ultraviolet, 603
    - , organic acid-modified, 438-440
    - , organic extending agents for, 286
    - , organic fillers for, 451-453
    - , packing for steam pipes from, 459
    - , paper pulp, filler, 365, 460, 461
    - , penetrating varnish from, 443
    - , phenol methylene ratio, 321
    - , phenolphthalamide-modified, 423
    - , phosphoric acid-modified, 439
    - , phthalides, softeners, 439
    - , pigmentation of, 564
    - , pine tar with, 461
    - , pitch with, 287
    - , plaster of Paris, 437
    - , plasticisers for, 235, 445, 529
    - , porous materials from, 457, 458
    - , Portland cement with, 457
    - , potassium chlorate, filler, 460
    - , powdered stone, filler, 461
    - , powdered tale, filler, 459
    - , polyalkylene oxide, plasticiser, 993

- Phenol-aldehyde resins, polyalkylene glycol aryl ether-modified, 430
- , polycondensation, modifier, 397
  - , polyhalohydrin-modified, 429
  - , polyhydric-alcohol-modified, 427-430
  - , polynuclear phenol, modifier, 408
  - , precipitation of, 362, 443, 456, 457
  - , precipitation of albuminoids with, 485
  - , urea-aldehyde hydrosols with, 475
  - , pressboard from, 470, 471
  - , printing matrices from, 459
  - , production data, 314
  - , properties of, 335, 1257
  - , protective colloids for, 326
  - , purification of, 335-339, 427
  - , pyromucic acid-modified, 439
  - , quartz with, 480
  - , reaction with glycerides and alcohols, 428
  - , — haloaliphatic acids, 427, 429
  - , — hydroxy sulphonic acids, 421
  - , — iodine and sulphur, 1192
  - , — metallic salts, 310
  - , — phenoxy aliphatic acids, 427
  - , — sulphur, 1192
  - , reducing sticking of, 373
  - , removal of excess phenol from, 365
  - , — neutral oils from, 362
  - , resin-acid salt-modified, 437
  - , resin ester modifiers, 400
  - , resistant to radium, 434, 438
  - , resistant to x-rays, 438
  - , rosin, modifier, 397, 398, 417
  - , rubber anti-oxidant from, 1192
  - , rubber-modified, 428, 432, 434-436
  - , rubber-vulcanization molds from, 459
  - , rubber with, 450, 484, 485
  - , safety-glass from, 480
  - , sealing compositions from, 424
  - , self-lubricating bearings from, 459
  - , shellac substitutes from, 284, 356
  - , short-cordage fibers, fillers, 461
  - , slag, filler, 461
  - , soap-modified, 438
  - , sodium borate-modified, 437
  - , sodium glycerate-modified, 429
  - , sodium-hydroxide modified, 437, 438
  - , sodium silicate with, 449
  - , softening agents for, 423-425, 432, 440, 441
  - , solid solvents for, 465
  - , solvents for, 397, 400, 405, 422, 443, 445, 446, 448
  - , sound records from, 476, 477, 624, 1335-1339
  - , Spanish rosin, modifier, 397
  - , spar varnishes from, 451
  - , spray-drying of, 340
  - , stages of conversion of, 444
  - , stearin pitch with, 487
  - , steel, filler, 460
  - , stencil sheets from, 452
  - , sucrose-modified, 429
  - , sulphonation of, 340, 418-421
  - , sulphonic acids in hardening of, 369
  - , sulphuric acid-resistant, 437, 438
  - , sunflower-husk resins with, 441
  - , tanning agent from, 340, 420
  - , tars as raw materials for, 360-364
  - , telephone diaphragms from, 460, 461
  - , tensile strength of, 338
  - , textile processing with, 639
  - , time of molding, 463, 464
  - , toluenesulphonyl chloride-treated, 422
  - , transfer sheets from, 452
  - , transparent, preparation, 365, 368, 369, 371, 428, 439, 467
  - , turnery stock, 467
  - , two-stage wet processes, 316-322
  - , urea resins with, 631
  - , use in cellulose lacquers, 445-448
  - , use of water in molding compositions, 438
  - , uses of, 235, 245, 1257
  - , varnishes from, 357, 443, 445
  - , veneers from, 478-479
  - , vinyl resins with, 445
  - , viscose films with, 452
  - , vulcanized rubber, filler, 459
- Phenol-aldehyde resins, wall tiles from, 463
- , waste distillates from, 320
  - , waterproof cement from, 479
  - , wax-modified, 320, 426, 427
  - , wood flour, filler, 461
  - , xerogels, 37
  - , x-ray resistant, 434, 460
  - , x-ray studies of, 87
  - , xylene, moderator, 328, 329
  - , zinc oxide-modified, 437, 438
- Phenol-aldehyde structures, porous, effect of catalysts, 487, 488
- Phenol-aldehyde-tung oil condensation products, 406
- Phenol-aldol resin, 392
- Phenol alkyl ethers, condensation with formaldehyde, 371
- Phenol-allyl alcohol resin, 394
- Phenol-alkyl halides, sulphonation of, 1133
- Phenolates, reaction with polyvinyl chloroacetate, 1034
- , reaction with urea-aldehyde resins, 665
  - , reaction with vinyl halides, 1008
- Phenol-benzal chloride resins, 1134
- Phenol-benzyl chloride condensation, 271, 1133
- Phenol-carbohydrate resins, limed, 438
- , uses of, 759, 760
- Phenol coefficient, definition of, 1187
- Phenol compounds, reaction with resins, 793
- Phenol content, effect on modified phenol-aldehyde resins, 430
- Phenol-o-cyclohexyl-cyclohexanol resin, 271
- Phenol-2,4-disulphonamide, resins from, 715
- Phenol esters, modifiers, phenol-aldehyde resins, 431, 432
- Phenol ethers, addition to formaldehyde-glycol-monoaryl ether reaction, 376
- , reaction with formaldehyde, 371, 376, 407
  - , reaction with o-phthalaldehydic acid, 439
  - , resins from, 714
- Phenol-ethylene oxide reaction, 255
- Phenol-fat mixtures, reaction with aldehydes, 421
- , reaction with sulphur chloride, 1188
- Phenol-formaldehyde-alkyd compositions, modified with phthalide, 942
- , modified with rosin, 936
  - , properties of, 934
  - , use as cement, 938
  - , use in coatings, 934-937
  - , use in moldings, 934, 937, 942
  - , use of boric acid in, 937
- Phenol-formaldehyde-benzotrichloride product, cold-molding composition, 1289
- Phenol-formaldehyde-carbohydrate resin, use of, 480
- Phenol-formaldehyde-colophony resins, modifiers for, 399, 400
- Phenol-formaldehyde-furfural resin, 527, 531, 532
- Phenol-formaldehyde-furfuramide resin, 536
- Phenol-formaldehyde-latex product, preparation and properties of, 1108
- Phenol-formaldehyde-linseed oil reaction, 405
- Phenol-formaldehyde reaction,  $\omega$ -amino-o-tolyl-o-hydroxybenzyl ether from, 309
- , automatic control by viscosity, 312
  - , cast resins from, 286, 287
  - , change of refractive index in, 50
  - , character of, 295
  - , 2,2'- and 4,4'-dihydroxy-dibenzylamines from, 309
  - , 4,4'-diphenylolmethane from, 299
  - , effect of alkali concentration, 292
  - , glycerol, 290
  - , heat, 353
  - , catalyst on, 291, 296, 299
  - , varying proportions, 297
  - , equation for, 301
  - , ether-extraction of colored compounds, 422
  - , gel from, 324
  - , initial products, 313
  - , in solvents, 405, 444
  - , kinetics of, 299
  - , methylene glycol methyl phenyl ether from, 280

- Phenol-formaldehyde reaction, neutral point in, 348
- , resols by, 444
  - , salgenin from, 281
  - , scheme of, 302
  - , stages of, 295, 300, 342
  - , time of heating, 319
  - , with  $\alpha$ -terpineol, 407
- Phenol-formaldehyde resin, absorption spectra of, 312, 313
- , action of sulphur chloride on, 1189
  - , action of ultraviolet radiation, 603
  - , acylation of, 422
  - , amber-like substance from, 319, 320
  - , amphoteric nature of, 310
  - , as fluxes, 692
  - , baking of molded products from, 318
  - , by one-stage process, 323, 324
  - , catalysts for alkylation of, 421
  - , celluloid substitutes from, 414
  - , change of constants during reaction, 299, 312
  - , coating aluminum with, 449
  - , comparison with furfural resins, 520
  - , —resorcinol-formaldehyde resins, 371
  - , —urea resin, 564
  - , condensation media, urea resins, 617
  - , condensation with cyclohexanone, 559
  - , constitution of micelles, 311
  - , cyclohexanol-modified, 417
  - , degradation products of, 292
  - , digester for, 325
  - , effect of carbolic acid on, 284
  - , —furfural in, 531
  - , —proportion of ammonia on, 312
  - , —urea on, 468, 469
  - , effect on drying oils, 413
  - , electrical tests on, 313
  - , emulsifying agents for, 417
  - , esterification with glycerol, 399, 400
  - , fillers for, 349, 352
  - , for injection molding, 1325
  - , furfural with, 526, 529, 532
  - , fusel oil with, 284
  - , hardening agents for, 357, 372, 373, 425
  - , hard-rubber substitute from, 415, 416
  - , hydrolysis of, 307
  - , incorporation with alkyl resins, 530, 934-938
  - , —aniline-furfural resin, 701
  - , cellulose acetate, 701
  - , cellulose ethers, 433
  - , chlorinated rubber, 435, 436, 1125, 1126
  - , cumarone resin, 134, 135, 141
  - , —ebonite, 426
  - , ester gum, 820, 821
  - , —factice, 1212
  - , furfural-phenol resin, 532
  - , —resorcinol-formaldehyde resin, 373
  - , rubber, 416, 1103
  - , —shellac, 415
  - , sulphurized hydrocarbon resin, 1202
  - , —urea resins, 608, 618
  - , —vinyl resins, 1041, 1044, 1050
  - , increasing elasticity of, 415, 441
  - , influence of electric field on, 311
  - , influence on alkyl resin formation, 864
  - , isolation of compounds from, 291, 292
  - , linen-laminated sheets from, 473, 474
  - , mechanism of hardening, 311
  - , modified with amines, 425, 426
  - , —aniline, 415, 425
  - , —casein, 417
  - , —chloroacetic acid, 938
  - , —gelatin, 415
  - , —glycerol, 415, 416, 428, 430
  - , —glycerol esters, 1004
  - , —oleic acid, 421
  - , —polyethyleneglycol esters, 430
  - , —polyvinyl alcohol, 665
  - , —proteins, 414-418
  - , —ricinoleic acid, 421
  - , —sulphated-mineral-oil polymer, 419, 420
  - , —sulphonated ricinoleic acid, 420
  - , —sulphur, 430, 441
  - , —thiourea, 435
  - , —toluenesulphonamide, 425
- Phenol-formaldehyde resin, modified with urea, 425, 672, 675
- , —viscose, 432
  - , modifiers for, 414, 415, 416
  - , neutralising excess formaldehyde, 425
  - , permanently fusible, 323, 324
  - , production by continuous process, 334
  - , properties of, 285, 287, 295, 296, 309, 414, 934
  - , purification, 296, 434, 936
  - , reaction with acids, 310
  - , —alcohols, 310
  - , —benzyl chloride, 1132
  - , —benzylphenylsulphonic acid, 419
  - , —cholesterol, 310
  - , —hexoses, 310
  - , —phenol-crotonaldehyde resins, 392
  - , —sodium sulphite, 420
  - , —tung oil, 403, 405
  - , shrinkage of, 1299
  - , softening agents for, 429
  - , solubilising by vulcanisation, 1207
  - , solvents for, 309, 318, 368, 423
  - , structure of, 297, 298, 311, 313
  - , suggested improvements, 315
  - , tall oil with, 757
  - , tartaric acid-modified, 284
  - , temporary binder, 1289
  - , tests for, 1256
  - , transparent, 430
  - , use in abrasives, 532, 1275
  - , —artificial leather preparation, 453
  - , —coating for rubber, 978
  - , —cold-molding compositions, 1287
  - , —floor-covering, 416
  - , —impregnating fibrous sheets, 440, 986
  - , —impregnating parchmentized fiber, 434
  - , —laminated glass, 963
  - , —non-breakable watch glasses, 988
  - , —rubber-compounding, 436
  - , —sandpaper, 1248
  - , —stencil paper, 424
  - , use with silicon in coatings, 961
  - , varnishes from, 10, 415, 474, 531
  - , viscosity of, 312
  - , vulcanized tars with, 426
  - , water-soluble salts of, 436, 488
  - , x-ray patterns of, 83-85, 87
- Phenol-formaldehyde-sulphur chloride resin, 1189
- Phenol-furfural-alkyl resin, compositions, 938, 939
- , fillers for molding of, 939
  - , use of phthalide in, 942
- Phenol-furfural-p-aminophenol, resin from, 531
- , resin in insulations, 531
- Phenol-furfural-benzaldehyde, reaction of, 531
- Phenol-furfural-coal tar, resin from, 531
- Phenol-furfural coatings by baking, 530
- Phenol-furfural reaction, black resin from, 528
- , catalysts for, 527, 528, 529
  - , control of, 528
  - , description of, 524
  - , hydrochloric acid as catalyst, 523, 526, 672
  - , oxalic acid as catalyst, 526
  - , resins from, 529, 530
- Phenol-furfural resin, application to moldings, 523
- , binders for paper, 533
  - , bonding agent for asbestos and graphite, 532
  - , coking of, 488
  - , cold-molded products from, 528
  - , hardening catalyst for, 529
  - , hard-rubber substitute from, 526
  - , hexamethylenetetramine as hardening agent, 532
  - , impregnant for cloth, 533
  - , impregnant for paper, 533
  - , in brake linings, 532
  - , in cellulose acetate lacquers, 531
  - , in cementing rubber to metal, 530
  - , incorporation with urea resins, 608
  - , in insulations, 523
  - , in protective coatings for cellulose esters, 530
  - , molding composition from, 523, 528, 529
  - , natural resin-modified, preparation, 424
  - , preparation of, 523, 527, 528, 530
  - , properties of, 523, 528, 529
  - , resistance to acids and alkalis, 528

- Phenol-furfural resin, sodium hydroxide as condensing agent, 532  
 —, solvents for, 526, 528, 530  
 —, varnishes from, 526, 528, 532  
 —, with alkyd resin in coating for candles, 965  
 —, with glycerol-phthalic anhydride resin, in insulating compositions, 530  
 —, —, in varnishes, 530  
 —, with phenol-formaldehyde resin, 532  
 —, with tung oil, 533  
 Phenol-furfural resinification, catalysts for, 522  
 Phenol-furfural resins, dimethylolurea-modified, 672  
 —, polyhydric-alcohol-modified, 428  
 —, tendency to gelatinize, 532  
 —, use of mold-lubricants, 1328  
 —, with cellulose acetate, lacquers from, 447  
 —, with nitrocellulose, lacquers from, 447  
 Phenol-glycerol resin, 391-393, 982  
 Phenol-glyoxylic acid resin, 376  
 Phenol-hexamethylenetetramine reaction, 327  
 Phenol-hexamethylenetetramine resins, action of sodium hydroxide on, 309  
 —, effect of carnauba wax, 425  
 —, —, rosin, 425  
 —, —, water, 328  
 —, glyceryl mono-oxalate-modified, varnish, 430  
 —, infusible, 310  
 —, modifier, urea-aldehyde resins, 678  
 —, use of mica filler, 425  
 —, water-repelling, 425  
 Phenol-hexamine bodies, stability of, 309  
 Phenol homologues, physical properties of, 366  
 —, reaction with formaldehyde, 324, 343  
 Phenolic compounds, action on rubber, 1102, 1103, 1104  
 Phenolic constituents in cashew-shell oil, 1229  
 Phenolic content of tars, 360, 361  
 Phenolic groups, in shellac, 1006  
 Phenolic hydroxyl groups, in resnotannol esters, 1193  
 Phenolic oils, from pyroligneous acid, 751  
 Phenolic styrenes, polymerization, 260, 261, 262  
 Phenol-indene ratio, effect in cumarone resins, 119  
 Phenol-ketone-formaldehyde resins, 390, 410  
 Phenol-lanolin-furfural, resin from, 531  
 Phenol-lead oxide resin, 273, 274  
 Phenol-lignin, constitution of, 747  
 Phenol-lignite molding composition, preparation of, 274  
 Phenol-lignite resin, comparison with phenol-aldehyde resins, 274  
 —, properties of, 275  
 Phenol-methylal resin, 394  
 Phenol-modified alkyd resins, 875  
 Phenol-modified-oil-extended alkyd resins, 875  
 Phenol- $\beta$ -naphthol-formaldehyde resin, 426  
 Phenol nuclei, union of, in phenol-sulphur chloride resins, 1184  
 Phenol-oil-aldehyde resins, 404, 406, 407  
 Phenol-oil mixtures, reaction with aldehydes, 421  
 Phenolphthalein, amorphous form, 1253  
 —, esters of, crystalline nature, 1252  
 —, —, resinous forms, 1252  
 —, ethers of, crystalline nature, 1252  
 —, —, resinous forms, 1252  
 —, polymeric form, 1252  
 —, reversion to crystalline form, 1252  
 —, sodium salt, reaction with toluyl chloride, 1252  
 —, use, films, 1252  
 Phenolphthalein di-m-methylbenzyl ether, non-crystalline, 1252  
 Phenolphthalein monomethyl ether, glass-like material, 1252, 1253  
 Phenolphthalein-m-toluate, molecular weight, 1252  
 Phenolphthalein tolylates, non-crystalline, 1252  
 Phenol-rosin condensation, in resin mixtures, 1133  
 Phenol-rosin esters, preparation, 797, 800  
 —, uses, 800, 824, 829  
 Phenol-resorcinol mixture, condensation with formaldehyde, 873  
 Phenol-rubber, thermoplastic material, 1104  
 Phenols, action of litharge on, 273  
 —, addition in cumarone polymerization, 118, 119  
 Phenols, addition to formaldehyde-glycol-monoaryl ether reaction, 376  
 —, alkylated, in coal-tar distillates, 361  
 —, —, properties of, 366  
 —, alkylation of, 410, 411  
 —, alkylation with alkyl halides, 411  
 —, —, octenes, 411  
 —, bromination of, 1154  
 —, catalysts for oxidation of, 271  
 —, chlorination of, 228  
 —, coal-tar, decolorization of, 361  
 —, —, purification of, 361  
 —, color test, 1259  
 —, effect of substituents on reactivity of, 366, 367  
 —, effect on chloroprene polymerization, 156, 157  
 —, esterification with rosin, 792, 793  
 —, extraction from coal tar, 362  
 —, —, shale oil, 364  
 —, fatty acids esterified with, 1233, 1234  
 —, fluxing agents, urea resins, 593  
 —, formation of polyalcohols of, 333  
 —, from hydrogenation of phenol-aldehyde resins, 307  
 —, from low temperature tar, 272, 408  
 —, from xanthorrhoea gum, 364  
 —, halogenated, amorphous compounds from, 379  
 —, —, reaction with aldehydes, 421  
 —, inhibitors, polymerization of furethylene, 243  
 —, —, polymerization of styrene, 242  
 —, modifiers, urea-aldehyde resins, 663, 675  
 —, oil-soluble, use of, in alkyd resins, 930  
 —, order of reactivity, 292, 247  
 —, oxidation of, 227, 271, 272  
 —, reaction with abietic anhydride, 800  
 —, —, acetaldehydesulphonic acid, 419  
 —, —, acetylene, 161  
 —, —, alcohol-modified urea-aldehyde resins, 665, 668  
 —, —, aldehyde-carboxylic acids, 375, 394  
 —, —, aliphatic dichlorides, 293  
 —, —, allyl alcohol, 393, 394  
 —, —, allyl esters, 394

—, flotation agent, 1190  
—, fly paper from, 1186  
—, hardening of, 1184, 1185, 1190  
—, hydrochloric acid in, 1186  
—, incorporation with cellulose derivatives, 1186  
—, incorporation with urea resins, 608  
—, lacquers from, 1186, 1193  
—, lakes from, 1187  
—, metal derivatives of, 1186, 1187  
—, modified, 1192-1193  
—, molding compounds, 1183, 1186, 1188, 1189, 1190, 1191, 1193  
—, mordants from, 1183, 1190, 1191, 1192  
—, preparation of, 1190-1193  
—, preventing crystallization of sulphur by, 1186  
—, relation of solubility to hardness, 1185  
—, relation to phenol-sulphur chloride resins, 1189, 1190  
—, removal of catalyst from, 1190  
—, — free phenol, 1190  
—, resorcinol ester substitutes, 1183  
—, solubility of, 1184, 1185, 1187, 1190, 1192, 1193  
—, structure of, 1189, 1190  
Phenol-sulphur resins, tanning agents, 1183, 1185, 1186, 1187, 1189, 1192, 1193  
—, tin compounds of, 1192  
—, use of reducing agent in preparation of, 1185  
—, uses of, 1186, 1188, 1189, 1190, 1191, 1192, 1193  
—, varnishes from, 1186, 1191  
—, wool-resist from, 1192  
Phenol-trichlorethylene condensation, 1128  
Phenol-urea-aldehyde resins, adhesives from, 676  
—, albumin-modified, 676  
—, alkyd-modified, 675  
—, binders for mica, 1274  
—, clarifying with thiourea, 675  
—, hardening agents for, 674  
—, milk-white, 674  
—, oxidation, 675  
—, preparation, 672, 673, 674, 675, 676, 677, 678  
—, protein-modified, 683  
—, rubber-like, 675  
—, sulphonated, uses, 676, 677, 678  
—, p-toluenesulphonamide-modified, 676  
—, uses, 672, 673, 674, 675, 676, 677, 678  
Phenol-urea-formaldehyde resin, solvents for, 676  
Phenol-urea-ketone resins, reaction, with aldehydes, 675  
Phenol-urea-toluene-sulphonamide mixture, reaction with formaldehyde, 425  
Phenol-wax mixtures, sulphonated, 421  
Phenoplast, defined, 315  
Phenoxyacetaldehyde, cumarone from, 93, 95  
Phenoxyacetic acid-formaldehyde resin, use in photographic plates, 375  
Phenoxy aliphatic acids, reaction with phenol-aldehyde resins, 427  
Phenoxybutyric acid, condensation with formaldehyde, 375  
Phenoxyethyl phthalate, softener for cellulose acetate lacquers, 970  
Phenoxyglycol acetate, from vinyl acetate and phenol, 1031  
Phenoxy-p-hydroxyphenylbutane, diarylbutane from, 301  
Phenoxypropene oxide, stabilizer, vinyl resins, 1050  
—, use with chlororubber, 1111  
Phenoxypropionic acid, condensation with formaldehyde, 375  
Phenyl acetate, from phenol and vinyl acetate, 1031  
—, solvent polyvinyl chloride, 1033  
Phenylacetonitrile, use in polymerization of 1,3-dienes, 163  
Phenylacetylene, catalysts for polymerization of, 162  
—, effect of ammonia on polymerization of, 162  
—, potassium hydroxide on polymerization of, 162  
—, — secondary and tertiary amines on polymerization of, 162  
—, polymerization, by heat, 162  
—, polymer of, solubility relations of, 162  
—, sym-triphenylbenzene from, 162  
Phenylacetylinaphthalene, condensation with Grignard reagents, 556  
Phenylacrylic acid esters, polymerized, use of, 1033  
2-Phenyl-4-aminoquinoline, condensation with acetic anhydride, 739  
1-Phenyl-4-anilinobutadiene, resin from, 733  
Phenyl-m-anisylacetaldehyde, resinification of, 509  
Phenylarsinic oxide, reaction with o-nitrodiazobenzene chloride, 727  
Phenylazide, addition of, to unsaturated systems, 847  
—, reaction of, with unsaturated phthalic anhydride, 846, 847  
Phenylazoxycarboxamide, action of alkali, 734  
Phenyl benzenesulphonate, effect on hardening of alkyd resins, 381  
Phenyl benzoate, 1135  
2-Phenyl-5-benzoylpyridine, reduction, resin formation, 738  
Phenylbenzyl ether, from reaction of benzyl chloride and phenol, 295  
γ-Phenyl-β-benzylpropane-β-diol, reaction with sulphuric acid, 991

- $\gamma$ -Phenyl- $\beta$ -benzyl- $\alpha,\beta$ -propylene oxide, preparation of, 991  
 Phenylbutadiene, reaction with acrolein, 831  
 Phenylbutadiene chloride, polymerization, 1253  
 Phenylbutadiene polymerization, aryl diazonium fluoborate catalyst in, 176  
 1-Phenylbutadiene, polymerization, 170  
 1-Phenylbutadiene polymer, molecular weight of, 170  
 —, vulcanization of, 183  
 2-Phenyl-1,3-butadiene, reaction with fumaric acid, 160  
 —, — maleic anhydride, 160  
 N-Phenyl- $\gamma$ -chloropyridinium chloride, resinification, 733  
 Phenyl cinnamate, from phenyl fumarate, 254  
 Phenylcyclohexanone, reaction with ethyl nitrite and potassium ethylate, 725  
 —, — nitrous vapors, 725  
 —, — wax from, 725  
 Phenyl diazonium fluoborate, action on indene, 103  
 —, catalyst, styrene polymerization, 241  
 Phenyl-eudekasaligenosalignin, reaction product, 329  
 p-Phenylene chains by Würtz-Fittig synthesis, 1141  
 Phenylendiamine, use of, in alkyd resins, 922  
 —, —, with chlororubber, 1111  
 m-Phenylendiamine, condensation with  $\beta$ -naphthol, 732  
 m-Phenylendiamine-furfural, light-sensitive material from, 539  
 p-Phenylendiamine, catalyst for furfural-phenol resin formation, 538  
 —, condensation with heptaldehyde, 705  
 —, hardening agent, 347  
 —, modifier, urea-furfural resins, 669  
 —, use, coloring phenol-aldehyde resins, 442  
 Phenylene ethers, condensation of, 55  
 Phenyl ester of cinnamic acid, polymerization, 1083  
 —, of  $\beta$ -methylcrotonic acid, polymerization of, 1083  
 Phenylethanol, bromo-derivatives of, bromostyrenes from, 254, 255  
 —, chlorination, chlorostyrenes by, 255  
 —, styrene from, 254  
 Phenyl ether, use of, in polymerization of, 1,3-diene, 182  
 Phenylethyl chloride, condensation by aluminum chloride, 1130  
 1-Phenyl-4-ethylcyclohexane-3,5-dione, reaction with oxygen, 560  
 Phenylethylene, 232  
 $\beta$ -Phenylethylphenylacetate, styrene from, 255  
 Phenyl fumarate, substituted, resins from, 1254  
 Phenylgermanium trichloride, reaction with metallic sodium, 1239  
 $\beta$ -Phenylglutaryl chloride, resinification, 1139  
 Phenyl groups, effect on polymerization tendency of butadiene, 170, 171  
 —, in polystyrene structure, 232, 233, 259  
 7-Phenyl-2,4,6-heptatrienal-1, formation of, 494  
 —, oxidation of, 495  
 —, resinification of, 510  
 Phenylhydrazine, condensation with benzoquinones, 561  
 —, — chloroacetophenone, 735  
 —, — 2-ethyl-1-hydrindone, 735  
 —, — toluquinones, 561  
 —, gum inhibitor, 223  
 —, reaction with acrolein, 504  
 —, — diversine, 745  
 —, — phorone, 736  
 —, — tetrahydro-furfural, 519  
 —, — tiglic aldehyde, 504  
 —, removal of acid by, 1024  
 —, use of, in alkyd resin production, 925  
 Phenylhydrazine hydrochloride, condensation with benzaldehyde, 736  
 Phenylisocamylthiocarbamide, reaction with bromine, 658, 733  
 —, resins from, 733  
 1-Phenyl-3-isobutenyl-5,5-dimethylpyrrolidine, from phorone and phenylhydrazine, 736  
 —, resin from, 736  
 sym-Phenylisobutylthiocarbamide, reaction with bromine, 658, 733  
 —, resins from, 733  
 Phenylmagnesium bromide, reaction with furylacetone, 519  
 Phenylmethylacetonitrile, reaction with sodium ethoxide and ethyl cyanoacetate, 733  
 Phenylmethylcarbinol, dehydration of, 255  
 —, distillation of benzoic ester of, 245  
 5-Phenyl-3-methylcyclohexanone dibromide, resinification, 560  
 Phenylmethylglycidol, use with chlororubber, 1111  
 Phenyl mustard oil, preparation of, 1197  
 —, reaction with di-o-tolylguanidine, 562  
 Phenyl- $\alpha$ -naphthylamine, condensation with triethanolamine, 732  
 Phenyl- $\beta$ -naphthylamine, condensation with acetone, 541  
 —, — aldol, 709  
 —, — butyraldehyde, 709  
 —, — formaldehyde, 709  
 —, effect on durability of rubber, 709  
 —, stabilization of butyraldehyde by, 497  
 5-Phenyl-2,4-pentadienal-1, reaction with acetaldehyde, 494  
 1-Phenylpenta-4-ene-1-yne, polymerization of, 162  
 3-Phenyl-2-pentene-1,5-oxide, resin from, 1254  
 o-Phenylphenol, reaction with formaldehyde, 377  
 Phenylphthalimide, modifier, phenol-aldehyde resins, 423  
 Phenylpropadiene, polymerization of, 155  
 N-Phenylpyridone, reaction with thionyl chloride, 738  
 Phenylpyrimidazole, reaction with phenacyl bromide, 739  
 2,3-(2'-Phenylpyrrolo-4',5')-N-methylquinoline, resinification, 742  
 Phenyl salicylate, condensation with formaldehyde, 374  
 trans-Phenylserine, benzoylation, resin formation, 733  
 Phenylsilicon trichloride, reaction with sodium, 1238  
 —, resin from, 1238  
 Phenylsilicon trichloride resin, molecular weight of, 1238  
 2-Phenyl- $\Delta^5$ -tetrahydro benzaldehyde, preparation of, 831  
 Phenylthiocarbamide, effect on polymerization of, 1,3-dienes, 184  
 Phenyl vinyl ether, boiling point of, 1008  
 —, decomposition of, 1009  
 —, from phenoxyglycol acetate, 1031  
 —, polymerization of, 1010  
 —, preparation of, 1008, 1009  
 Phenyl vinyl ketone, condensation, 556, 562  
 —, from  $\omega$ -dimethylaminopropiophenone hydrochloride and steam, 557  
 —, reaction with alcohol, 557  
 Phloroglucinol, color tests, 1259  
 —, modifier, urea-aldehyde resins, 674  
 —, reaction with acetylene, 383  
 —, — formaldehyde, 279, 280  
 —, — hexamine, 310  
 Phloroglucinol-aldehyde condensations, 761  
 Phloroglucinol-formaldehyde-dimethylamine hydrochloride condensation, 310  
 Phloroglucinol-furfural reaction, resin from, 525  
 Phloroglucinol-sugar condensations, 761, 762  
 Phonograph needles, from alkyd resins, 983  
 Phonograph records, 1265  
 —, copal esters binder, 829  
 —, fillers for, 1275  
 —, from furfural resin, 533  
 —, from Ololive, 1053  
 —, from rubber, 1093  
 —, from shellac, 24, 476  
 —, molding of, 464, 1334, 1335, 1336, 1337, 1338, 1339  
 —, resin surfaces for, 476, 477, 1202  
 —, steel dies for, 1336  
 —, vinyl resins in, 1269  
 Phorone, analogues, from cyclohexanone, 558  
 —, condensation with furfural, 533  
 —, from acetone and zinc chloride, 541  
 —, from keto-alcohols, 540

- Phorone, reaction with cresol, 387  
 —, — phenylhydrazine, 736  
 —, — resin, 803  
 —, reduction with sodium amalgam, 541  
 —, stability toward polymerisation, 562  
 Phorone dinitroschloride, from acetone, 725  
 —, resinification, 725  
 Phosgene, phenol esters of abietic acids with, 797  
 —, reaction with ethylene glycol, 870  
 —, — glycerol, 885  
 —, — salicylic acid, 375  
 —, use, acylation of phenol-aldehyde resins, 422  
 Phosphate buffers, polymerization of dimethylol-urea, 614  
 Phosphates, aryl, modifiers, phenol-aldehyde resins, 481  
 Phosphatised surfaces, varnish tests on, 1368  
 Phosphomolybdic acid, catalyst, curing, cellulose-urea resin compositions, 622  
 Phosphorescent coatings, resin esters in, 823  
 Phosphoric acid, action on chlororubber paints, 1121  
 —, — cumarone, 94  
 —, — indene, 102  
 —, activator, for hydrogenation of esters, 807  
 —, catalyst, condensation, phenol and tung oil, 403, 404  
 —, —, —, phenol and vinyl esters, 1031  
 —, —, —, urea and formaldehyde, 539, 604  
 —, —, —, cumarone polymerisation, 120  
 —, —, —, curing, cellulose-urea resin composition, 622  
 —, —, —, dehydration of ethyl hydracrylate, 1074  
 —, —, —, formaldehyde-diphenylol cyclohexane reaction, 377  
 —, —, —, hydrocarbon-aldehyde condensations, 264  
 —, —, —, in phenol-acetone reaction, 389  
 —, —, —, phenol-alcohol resins, 333  
 —, —, —, phenol-aldehyde reaction, 430, 439  
 —, —, —, phenol-formaldehyde reaction, 349, 353  
 —, —, —, polymerization of diolefins, 185  
 —, —, —, preparation, polyvinyl acetals, 1062  
 —, —, —, resin formation, 278  
 —, —, —, resorcinol-acetone condensation, 373  
 —, —, —, urea-aldehyde reaction, 673  
 —, —, —, condensing agent, adipic acid and 1,3-butylene glycol, 898  
 —, —, —, amines and aldehydes, 707  
 —, —, —, dehydrating agent, preparation of unsaturated keto-alcohol, 844  
 —, —, —, dehydration of phenylmethylcarbinol, 255  
 —, —, —, esterification of phenol-alcohols with, 399  
 —, —, —, hardening agent, phenol-ketone-aldehyde resins, 390  
 —, —, —, urea-formaldehyde resins, 598  
 —, —, —, in rosin distillation, 779  
 —, —, —, reaction with ethylidene diacetate, 1019  
 —, —, —, fatty acid esters, 1238  
 —, —, —, furfural, 1181  
 —, —, —, indole, 743  
 —, —, —, resin purification with, 467  
 —, —, —, solubilization of castor oil with, 1223  
 —, —, —, styrene from chloroethylbenzene with, 253  
 —, —, —, use in bleaching alkyl resins, 908  
 —, —, —, with modified urea-aldehyde resin, 685  
 Phosphorus, catalyst, rubber iodination, 1114  
 —, —, plastics from, 32  
 Phosphorus chlorides, catalysts for chlorination, 1151  
 Phosphorus compounds, organic, 1240-1241  
 —, —, resinous, 1235  
 Phosphorus fluorides, addition to boron-trifluoride catalyst, 166  
 Phosphorus halides, oxygenated, reaction with rubber, 1116  
 Phosphorus nitrile chloride, properties of, 1240  
 Phosphorus oxychloride, action on cumarone, 95  
 —, —, p-hydroxybenzoic acid, 378  
 —, —, —, rubber, 1101  
 —, —, —, catalyst, phenol-acetaldehyde reaction, 382  
 —, —, —, phenol-formaldehyde reaction, 357  
 —, —, —, polymerization of 1,3-dienes, 183  
 —, —, —, dehydration of sodium salicylate with, 277  
 —, —, —, in esterification of cork meal, 750  
 —, —, —, reaction with hydroxy sulphonic acids and phenolic resins, 431  
 —, —, —, sodium acrylate, 1074  
 Phosphorus pentachloride, action on alkylfuryl-carbinols, 520  
 —, —, —, rubber, 1101  
 —, —, —, terpenes, 783  
 —, —, —, catalyst, chlorination, 1154  
 —, —, —, chlorination of ethylbenzene, 253  
 —, —, —, condensation, 3,3,4,4-tetraphenylcyclobutane-1,2-dione, 533  
 —, —, —, in polycyclopentadiene formation, 188  
 —, —, —, phenol-formaldehyde reaction, 357  
 —, —, —, reaction with cholesterol, 1240  
 —, —, —, homophthalic anhydride, 1240  
 Phosphorus pentachloride-acetophenone reaction, 1,1-dichloroethylbenzene from, 253  
 Phosphorus pentasulphide, action on rubber, 1101  
 Phosphorus pentoxide, action on unsaturated hydrocarbons, 225  
 —, —, catalyst, benzyl alcohol condensation, 1007  
 —, —, —, paraformaldehyde-tetrahydronaphthalene condensation, 265  
 —, —, —, polymerization of carbon suboxide, 1014  
 —, —, —, —, of 1,3-dienes, 183, 187  
 —, —, —, resorcinol-ethyl cyclohexanone-2-carboxylate reaction, 391  
 —, —, —, dehydrating agent for  $\alpha$ -hydroxybutyric acid, 1080  
 —, —, —, effect on cumarone polymerization, 106  
 —, —, —, eugenol resinified with, 260  
 —, —, —, in absorption tests, 1344  
 —, —, —, oxidation of mixture of phenol and o-cyclohexyl-cyclohexanol, 271  
 —, —, —, reaction with sweet almond oil, 1253  
 —, —, —, use, reaction of cresol with dimethylolurea-glycerol compound, 668  
 Phosphorus pentoxide and glycollic acid, action on naphthalene, 266  
 Phosphorus sulphide, in plastic sulphur, 1164  
 —, —, wood preservative, 1165  
 Phosphorus tribromide, bromoethers from, 1008  
 Phosphorus trichloride, action on diethylaniline, 689  
 —, —, —, rubber, 1101  
 —, —, —, reaction with bis(3-hydroxypropyl) sulphide, 1179  
 —, —, —, polyacrylic acid, 1075  
 Phosphoryl halide, action on rubber, 1101  
 Phosphotungstic acid, flocculant, methylolureas, 595  
 Photocatalysts, for styrene polymerization, 240  
 Photo-elasticity tests, use of polarized light, 469  
 —, —, with transparent models from phenol resins, 469  
 Photo-engraving, use of sensitized phenol resins in, 453  
 Photographic coating, use of synthetic resins, 1251  
 Photographic film, cushioning stratum in, 1099  
 —, —, ester gum solution as coating, 827  
 Photographic films, protection by anti-halation layer, 854  
 —, —, treated with sulphonamide resins, 722  
 —, —, urea resins in, 648  
 —, —, use of alkyl resins in, 968  
 —, —, polyvinyl alcohol, 1059  
 —, —, —, water-soluble salts of polyacrylic acid in, 1079  
 Photographic filters, acetaldehyde resin in, 495  
 Photographic paper, coated with vinyl resins, 1043, 1050  
 —, —, —, waterproofing, 1127  
 Photographic plates, anti-halation, resins for, 375  
 Photography, cumarone resin in, 140  
 —, —, furfuralamine resins in, 538  
 Photolysis, of acetaldehyde vapors, 494  
 Photomechanical printing, use of resin coatings, 1251  
 Photopolymerisation, of acrylic acid, 1071  
 —, —, of allyl acrylate, 1073  
 —, —, of indene, 101  
 —, —, vinyl acetate, effect of oxygen, 1020  
 o-Phthalaldehyde acid, reaction with phenols, 439  
 Phthalate plasticisers, resorcinol test for, 957  
 Phthalate resin, test for, 957  
 Phthalates, color tests, 1259  
 —, —, plasticisers, modified urea-aldehyde resins, 679  
 —, —, reaction with phenols, 1259

- Phthalic acid, catalyst, urea-aldehyde reaction, 663  
 —, condensation with polyhydroxy acids, 910  
 —, effect on softening point of amine-aldehyde resins, 696  
 —, esterification of phenol-alcohols with, 399  
 —, from naphthalene, 263  
 —, from resinene, 276  
 —, hardening agent, urea resin, 618  
 —, modifier, phenol-aldehyde resins, 439  
 —, monoalkyl esters of, 950  
 —, overcoming stickiness of rubber coatings by, 1093  
 —, quantitative determination, 1260  
 —, reaction with lead acetate, 957  
 —, softening agent for nitrocellulose film, 970  
 —, use in alkyd resins, 876, 969  
 Phthalic acid alkyl amine salts, properties of, 954  
 Phthalic acid esters, use with chlororubber paints, 1123  
 Phthalic acid-glycerol esters, condensation media, urea resins, 617  
 Phthalic acid monoglyceride, nature of, 862, 863  
 Phthalic anhydride, catalyst, urea-phenol-aldehyde reaction, 676  
 —, condensation with alcoholamines, 904  
 —, — 1,3-butylene glycol, 898  
 —, — 2,3-butylene glycol, 898  
 —, — casein, 732  
 —, — elastin, 732  
 —, — ethanolamines, 904  
 —, — ethylene glycol, 897, 902  
 —, — ethylene oxide, 898  
 —, — fibrin, 732  
 —, — glycerol, 646, 876, 878, 879, 882, 886, 887, 899, 902, 903  
 —, — glycerol  $\beta$ -hydroxyethyl ether, 899  
 —, — glycerol monoethyl ether, 900  
 —, —  $\alpha$ -glyceryl phenyl ether, 900  
 —, — glyceryl tetrahydrofurfuryl ether, 900  
 —, — hexahydroxycyclohexane, 904  
 —, — keratin, 732  
 —, — pentaerythritol, 901  
 —, — propane-1,2-diol, 898  
 —, — triethanolamine, 904  
 —, — triethylene glycol, 898  
 —, — trimethylene glycol, 898  
 —, control of pH with, 353  
 —, fluorescein test for, 957  
 —, from anthracene, 883  
 —, in carbohydrate resins, 757  
 —, modifier, phenol-aldehyde resins, 439  
 —, —, urea-aldehyde resins, 663  
 —, neutralizing agent, 345  
 —, polymerization of dimethylolurea by, 609, 610  
 —, raw material for resin production, 9  
 —, reaction with butyl alcohol, 902  
 —, — castor oil, 909  
 —, — cellulose, 904  
 —, — cetyl alcohol, 903  
 —, — dextrose, 761  
 —, — 3-ketobutanol, 543  
 —, — lauryl alcohol, 903  
 —, — resorcinol, 957  
 —, — terpene hydrate, 903  
 —, removal from resins, 912  
 —, resins by condensation with phenol alcohols, 287, 288  
 —, softener for rubber products, 1098  
 —, use, 323  
 —, —, in preparation of alkyd resins, 945, 954  
 Phthalic anhydride and 9,10-dihydroxystearic acid composition, modified with drying oils, 911  
 Phthalic anhydride-coconut oil-diethylene glycol balsam, preparation of, 968  
 Phthalic anhydride-ethylene glycol resin, in cellulose acetate lacquers, 966  
 Phthalic anhydride-glycerol resin, modifier, phenol-urea-aldehyde resin, 675  
 —, —, with nitrocellulose in lacquers, 958  
 Phthalic anhydride-glycerol-salicylic acid, preparation of resin from, 931  
 Phthalic anhydride- $\beta$ -sulphonic acid-sulphuric acid mixture, use in sulphonation, 910  
 Phthalic-benzoic-glycerol resin, in nitrocellulose lacquers, 966  
 Phthalic-diethylene glycol resin, insulating material, 986  
 Phthalic esters, fluxing agents, 337  
 —, plasticizers, 897  
 —, —, for polyacrylic ester sheets, 1078  
 Phthalic glyceride, formation of, 862  
 —, modified with shellac, 913  
 —, preparation, 876  
 —, solubility in drying oils, 921, 925, 930, 931, 932  
 Phthalic-glyceride-cottonseed oil resin, in coating compositions, 968  
 Phthalic glyceride resins, arcing resistance, 1347  
 —, modified with drying oils and drying oil acids, 918-933  
 —, reaction with ethylene oxide, 993  
 Phthalic glyceride rosin composition, preparation of, 912, 913, 914  
 Phthalic glyceride soya bean oil acid resin, production of, 921  
 Phthalic glyceride walnut oil fatty acid resin, production of, 921  
 Phthalic glycerol resins, artificial silk from, 965  
 —, as coatings for candles, 964  
 —, rubber cement, 965  
 Phthalic glycol, compatibility with cellulose acetate, 897  
 —, —, nitrocellulose, 897  
 Phthalide, modifying agent for glycerol phthalate resin, 970  
 —, properties of, 941  
 —, use in alkyd-modified urea-aldehyde resin, 663  
 —, — aminoketone resins, 942  
 —, — itaconic acid resins, 942  
 —, — phenol-aldehyde-alkyd resins, 942  
 —, — styrene resins, 942  
 —, — tung oil-toluidine resins, 942  
 Phthalide-modified alkyd resins, itaconic acid polymers, modifier, 1086  
 Phthalide-phthalic-glyceride, plasticizer for polystyrene, 247  
 Phthalides, as plasticizers, 120, 439  
 —, preparation, 439  
 —, substituted, structure of, 941  
 —, use in alkyd resins, 941  
 Phthalimide, reaction with formaldehyde, 573  
 o-Phthaloyl chloride, reaction with benzyl acetate, 1254  
 Phthalyl chloride, action on rubber, 1100  
 —, reaction with magnesiylindole, 743  
 Phthalyl gumme-amine picrate, preparation, resins from, 1254  
 Physiological specimens, preservation with urea resins, 647  
 Picoline resins from, 204  
 $\alpha$ -Picoline, reaction with alkali iridohexachlorides, 739  
 $\alpha$ -Picolinic acid, formation of, 850, 851  
 Pickling agent, polyethylene oxide in, 993  
 Pickling inhibitor, amine-aldehyde resin, 703, 710  
 —, from o-toluidine, 1193  
 Picric acid, action on indene, 99  
 —, condensing agent, amine-aldehyde reaction, 707  
 —, in isolation of cumarone, 93  
 —, precipitant for albumin-ethylene oxide product, 993  
 Piercing potential, of polystyrene, 236  
 Pigmentation, of moldings, 1276  
 —, of phenol-formaldehyde resins, 564  
 —, of urea resins, 607  
 Pigmented coating, for automobiles, Rezyls in, 956  
 —, non-caking, 979  
 Pigments, dispersions of, preparation of, 200  
 —, effect on gloss of oil cloth, 137  
 —, — hardness of varnish, 1371  
 —, — light-stability of chlororubber, 1119, 1120  
 —, — translucency of urea resins, 621  
 —, for Glyptal enamels, 961  
 —, luminous, polystyrene base for, 247  
 —, use of polyethylene oxide in, 993  
 —, wash-fast, use of urea resins, 643  
 Pillow stuffing, from chlororubber, 1123  
 Pimelic acid, esterification of, 814  
 Pimelic acid, formula for, 883  
 —, use in alkyd resins, 908

- Pimelic anhydride, reaction with water, 996  
 Pinabietic acid, in sulphite liquor, 734  
 Pinacol, 2,2-dimethylbutadiene from, 177  
 Pinacolin, condensation with furfural, 538  
 —, decomposition of, 532  
 Pinene, catalyst for polymerisation of, 176  
 —, co-polymerisation with diolefins, 192  
 —, esterification of, 814  
 —, in turpentine, 780  
 —, reaction with formaldehyde, 782  
 —, — with oxalic acid, 783  
 —, sulphurisation of, 1200  
 Pinene dichloride, formation of, 783  
 Pinene hydrochloride, incorporation with rubber, 1104  
 —, resinification of, 1137  
 Pinene ozonide, catalyst, for phenol-formaldehyde reaction, 358  
 $\alpha$ -Pinene, isomerized, preparation of, 844  
 —, —, reaction with maleic anhydride, 844  
 $\alpha$ -Pinene-maleate, preparation of, 845  
 —, esterification of, 845  
 $\beta$ -Pinene, reaction with maleic anhydride, 845  
 Pine oil, constituents of, 780  
 —, cutting oil from, 1200  
 —, dehydration of, 782  
 —, effect of fuller's earth, 782  
 —, flotation agent from, 1200  
 —, oxidation of, 781, 782  
 —, plasticizer, for vulcanized rubber, 1115  
 —, polymerization of, 781  
 —, production of, 780  
 —, reaction with paraform, 782  
 —, — with phenols, 783  
 —, — with polyvinyl chloride, 1038  
 —, sulphurization of, 1200  
 Pine resin, in sealing wax, 1150  
 Pine tar, action of stannic chloride on, 215  
 —, distillation of, 752  
 —, drying oil from, 781  
 —, hardened by lime, 752  
 —, use of, as rubber softener, 105, 1098  
 —, —, with alkyl resins, 943  
 —, —, with chlororubber, 1119  
 —, —, with phenol resin, 461  
 Pine-tar oil, in rubber composition, 1200  
 —, sulphurization of, 1200  
 Pine wood, resins from, 749  
 —, steam distillation of, 780  
 Pinocampnone, formation of, 783  
 Pinocarveol, pinocampnone from, 783  
 Pinolin, from rosin oil, 779  
 Pintsch gas, "hydrocarbon drips," resins from, 121  
 Piperazine-formaldehyde-phenol resins, as rubber anti-agers, 377  
 Piperidine, catalyst, cresol condensation, 347  
 —, —, ketone-aromatic aldehyde reaction, 557, 563  
 —, —, ricinoleic acid condensation, 1224  
 —, effect of, on polymerisation of phenylacetylene, 162  
 —, reaction with 6-nitropiperonal, 738  
 —, — with furfural, 707  
 —, — with 2,7-dibromo-4,6-dinitroanthene, 738  
 —, use in resinification of styryl methyl ketones, 563  
 —, — in vulcanization of polyvinyl alcohol, 1050  
 Piperidine-carbon disulphide, addition product, hardening agent for shellac, 703, 1237  
 Piperidine dithiocarbamates, catalysts, phenol-aldehyde reaction, 345, 348, 469  
 Piperidine-formaldehyde-phenol resins, as rubber anti-agers, 377  
 Piperitone, reaction with oxygen, 558  
 Piperonal, condensation of, 509  
 Piperonylmethylpropylene glycol, resinification of, 510  
 Piperylene, polymerisation of, 169  
 Pipes, extrusion of, 1323  
 —, lining with sulphur, 1165  
 —, protective coatings for, 1147, 1377, 1378  
 —, rubber-resin composition, 1246  
 —, water mains, molded, 1333  
 Pipe stems, from resorcinol-formaldehyde resin, 371  
 Piston segments, from laminated materials, 937  
 Pitch, coal-tar, chlorinated, 1156  
 —, —, coking of, 360  
 —, —, uses of, 274, 360  
 —, definition of, 13  
 —, from halogenated paraffin, 1158  
 —, from rosin oil, 780  
 —, from still-residues, 121  
 —, from wash-oil, 122  
 —, hard-wood, in sound records, 1335, 1336  
 —, plasticity of, 32  
 —, reaction with vegetable oils, 274  
 —, resinous materials from, 274  
 —, rubber substitute from, 1204  
 —, use of, in cold-molding, 1317  
 —, —, with alkyl resins, 943, 966  
 —, —, with cashew-shell oil, 1230  
 —, —, with phenol-aldehyde resins, 286, 287, 329, 332  
 —, —, with sulphur, 1162  
 —, vulcanized, use with phenol-aldehyde resins, 426  
 Pitch-asphalt mixture, modifier, phenol-aldehyde resins, 426  
 Pitch binders, replacement of, in cold-molding compositions, 1237  
 Pitches, fatty, solubilizing, 1251  
 Pitchy material, removal from tall oil, 756  
 Pitting, of moldings, 1320  
 —, of varnish films, 36  
 Plant diseases, copper salts of cumarone resins in combating, 121  
 Plant material, utilization for resins, 762  
 Plaskon, urea-aldehyde resin molding composition, 565, 628  
 Plaster of Paris, in cold-molding compositions, 1235  
 —, molds, use of, 464, 465  
 —, sulphur in, 1168  
 —, use, phenol-aldehyde composition, 437  
 Plastering, use of, 1313  
 Plastering method, of forming tanks, 1332  
 Plasticity, and elastic limit, 34  
 —, and shearing stress, 34  
 —, colloidal, nature of, 32  
 —, definition of, 31, 34  
 —, influence of close packing, 32  
 —, — mechanical effect, 32  
 —, — particle size, 33  
 —, measurement of, 34, 1358  
 —, of amorphous materials, 31  
 —, of crystals, 31  
 —, of glass, 31, 32  
 —, of metals, 31, 32  
 —, of methyl rubber, 178  
 —, of paints, 35  
 —, of pitch, 32  
 —, of shellac, 32  
 —, of solids, 31, 34  
 —, of urea resins, effect of pH, 606  
 —, —, of water, 619  
 —, of viscous liquids, 31, 34  
 —, of wax, 31  
 —, principle of conformation in, 33  
 —, relation to thixotropy, 32  
 —, thermal, 31, 33  
 Plasticizer, for sulphur, 1231  
 Plasticizers, see also Softening agents  
 —, determination of, 1261  
 —, effect in lacquers, 827, 959  
 —, for alkyl resins, 942, 960, 966  
 —, for artificial silks, 1153  
 —, for butadienol-ester polymers, 152  
 —, for cellulose acetate, 820, 717, 719, 730, 896, 970, 1231  
 —, for cellulose acetate-sulphonamide aldehyde mixtures, 717, 718  
 —, for cellulose esters, 719, 896, 1231  
 —, for cellulose ethers, 112, 896, 963, 1231  
 —, for chlororubber, 965, 1118, 1119  
 —, for cumarone resins, 120, 137  
 —, for nitrocellulose, 836, 909, 966, 970, 993, 1206, 1240  
 —, for phenol-aldehyde resins, 355, 344, 354, 357, 367, 402, 445, 446, 447, 468, 479, 486, 533, 702, 903  
 —, for polystyrene, 227, 245, 246, 247, 248, 251  
 —, for rubber, 789, 1231

- Plasticisers, for shellac, 1335  
 —, for sulphonamide-aldehyde resins, 718  
 —, for urea resins, 632, 633  
 —, for wood pulp plastics, 748  
 —, use in molding compositions, 1276, 1277  
 Plastic material, process of forming, 33  
 —, strength of, 31, 22  
 Plastic sulphur, 1162  
 —, combination with coal tar, 1163  
 —, combination with paraffin wax, 1163  
 —, crystallisation retarders, 1162  
 —, incorporation with cumarone resins, 1162  
 —, stabilisers for, 1164  
 —, stable form, 1163  
 —, temperature of crystallization, 1162  
 Plastics, definition of, 13  
 —, effect of working, 1223  
 —, influence of particle size on, 32  
 —, molded articles from, 13, 14  
 —, pseudo, nature of, 34, 35  
 Plasto resins, compatibility with cellulose acetate, 966  
 Plastopals, urea-aldehyde resins, 634, 635  
 Platens, methods of heating, 463, 1305  
 Plate glass, substitutes, urea-formaldehyde resins, 600  
 Plates, of synthetic resins, use of, 1248  
 —, from lignite phenol resins, 275  
 Platinum, catalyst, acetylene-aniline condensation, 704  
 —, —, cumarone polymerization, 118  
 —, —, drying oil polymerisation, 1228  
 —, —, hydrogenation of esters, 807  
 —, —, oxidation of phenol, 271  
 Platinum black, preparation of, 1095  
 —, reducing agent for rubber, 1035  
 Platinum dichloride, reactions with acetone, 541  
 Platinum oxide, catalyst, hydrogenation of furfural, 519  
 Plumbing fixtures, from urea resins, 627  
 Polarity, in gelation of drying oils, 1226  
 —, in polymeric chains, 41  
 —, of alkyd resins, 868  
 —, of phenol-aldehyde resins, 313  
 —, of polystyrene, 236  
 Polarized light, use of, photo-elasticity tests, 469  
 —, —, testing resins, 1262  
 Polishes, from amides of esterified waxes, 815  
 —, from chloronaphthalenes, 1153  
 —, from ester gum, 827  
 —, from fat-resin-wax mixtures, 1251  
 —, from montan wax, 814  
 —, from phenol-aldehyde resins, 284, 367, 447  
 —, from polyvinyl ethers, 1011  
 —, from vinyl ester-aldehyde resins, 1065  
 —, polyethylene oxide in, 993  
 Polishing, of chlororubber paints, 1120  
 —, of moldings, 1315, 1330  
 —, of molds, 22, 1304  
 —, of urea resin lacquers, 634  
 "Pollopal," molding composition, urea resins, 629  
 Polyoacnaphthalene, from acenaphthalene, 260  
 Polyoacetaldehyde, reduction of, 1062  
 Polyacrylates, as dispersing agent, 1075  
 —, sound records from, 1078  
 Polyacrylic acid, preparation of, 1069, 1072, 1075  
 —, reaction with organic bases, 1072  
 —, — thionyl chloride, 1075  
 —, solvents for, 39, 1071, 1072  
 —, stability of, 1072  
 —, structure of, 1069  
 —, water-soluble salts, preparation, 1075  
 —, —, uses, 1072, 1079  
 Polyacrylic acid chloride, reaction with aniline, 1076  
 Polyacrylic acid derivatives, as adhesives, 1077  
 —, coatings from, 1078  
 —, compatible with chlororubber, 1119  
 —, molding composition from, 1078  
 Polyacrylic anhydride, preparation, 1075  
 Polyacrylic esters, as adhesives, 1077, 1078  
 —, from polymeric acids, 1075  
 —, glass substitute, 1078  
 —, instability of high polymers, 1073  
 Polyacrylic esters, rubber substitutes from, 1078  
 —, solvents for, 1071, 1073  
 Polyacrylic ester sheets, plasticizers for, 1078  
 Polyacrylonitrile, hydrolysis of, 1072  
 Polyacrylonitrile, reaction with alkalies, 1075  
 Polyalcohols, branched-chain resin from, 283  
 —, of phenols, 333  
 —, reaction with rosin, 802  
 Polyalkylene glycol aryl ethers, modifiers, phenol-aldehyde resins, 430  
 Polyalkylene oxalates, formation of, 871  
 Polyamides, binding units of, 1000  
 —, comparison with polyesters, 999  
 —, distillation of, 1000  
 —, effect of heat on, 1000  
 —, fibers from, 1000  
 —, from acrylic acid derivatives, 1075  
 —, from  $\epsilon$ -aminocaproic acid, 999  
 —, physical properties of, 1000  
 —, structure of, 999  
 Polyaminocaprylaminoacproic acid, preparation, 999  
 Polyaneethole, from anethole, 261  
 trans-Polyanhydride, from cis-p-hexahydroterephthalic acid, 999  
 Polyanhydride of adipic acid, reaction with aniline, 998  
 —, of sebacic acid, preparation of, 997  
 Polyanhydrides, from cyclic dibasic acids, 999  
 —, polyesters from, 999  
 —, reaction with benzene, 998  
 —, structural unit of, 997  
 Polybasic acid poly-ester resins, constituents, 1287  
 —, uses, 1286  
 Polybasic acid poly-esters, analytical scheme, 1286  
 Polybasic acid-polyhydric alcohol esters, modifiers, urea-aldehyde resins, 665, 666, 668  
 Polybasic acids, alkyd resins from, 10  
 —, as polyfunctional derivatives, 862  
 —, condensation with carbohydrates, 877  
 —, — polyhydric alcohols, 376  
 —, esterification with monohydric alcohols, 862  
 —, organic, urea-formaldehyde condensation, 611  
 —, use in hydrolyzing drying oils, 928  
 Polybromoprene, density of, 159  
 —, formation of, 159, 160  
 Polycarboxylic ketones, modifiers, for ester gum, 805  
 Polychlorinated paraffins, reaction with alkalies, 1178  
 $\alpha$ -Polychloroprene,  $\mu$ -polychloroprene from, 156, 157  
 —, isolation of, 156  
 —, production of, 157  
 —, properties, 157, 158  
 —, uses, 157, 159  
 $\beta$ -Polychloroprene, constitution of, 173, 174  
 —, preparation, 173  
 $\mu$ -Polychloroprene, from  $\alpha$ -polychloroprene, 156, 157  
 —, structure of, 156, 174  
 $\omega$ -Polychloroprene, resemblance to methyl rubber H, 177  
 Polycumarone, modifier, for phenol-aldehyde resin, 397  
 "Polycumarones," 96  
 Polycyclopentadiene, applications for, 188  
 —, effect of chemical reagents on, 188  
 —, effect of drying on, 188  
 —, formation in gas mains, 183  
 —, from cyclopentadiene, 187, 188  
 —, oxide of, 188  
 —, resemblance to rubber, 188  
 —, solubility relationships of, 58, 188  
 —, structure of, 58, 188  
 —, x-ray studies of, 46  
 Polycyclorubber, formation of, 1089  
 Polydimethylenes, hydrogenation of, 580  
 —, structure of, 580  
 Polydivinylbenzene, coating compositions from, 249  
 Polyester fatty acid glycerides, from estolides of castor oil, 1222  
 —, uses of, 1222  
 Polyester-polyamides, preparation of, 999-1000  
 —, physical properties of, 1000

- Polyesters, decomposition of, 999  
—, extrusion of, 998, 999  
—, filaments from, 998, 999, 1000, 1002  
—, from glycol-polybasic acid reaction, 998, 999  
—, from hydroxy acids, 999, 1000, 1001  
—, from polyanhydrides, 999  
—, of polymethylenes, properties, 872  
—, physical properties of, 999  
—, structure of, 1000, 1002  
Polyethylene acetate, preparation of, 990  
Polyethyleneglycol acetate, modifier, phenol-aldehyde resins, 430  
Polyethyleneglycol cresyl ether, modifier, 430  
—, preparation, 430  
Polyethylene glycols, cleansing agents from, 993  
—, foaming agents from, 993  
—, preparation of, 990  
—, reaction with non-carbohydrate compounds, 993  
—, wetting agents from, 993  
Polyethylene oxide, properties of films, 991  
—, solubility of, 990, 991  
—, structure of, 74, 75, 990, 991, 992  
—, viscosity of, 74, 75, 991  
—, x-ray studies of, 75, 991  
—, yields of, 991  
Polyethylene oxide chlorohydrate, preparation of, 992  
Polyethylene oxides, acetylation of, 992  
—, as dispersing agents, 993  
—, as dyeing assistants, 993  
—, as pastes, 993  
—, as plasticizer, 993  
—, as wood filler, 993  
—, derivatives of, 992-994  
—, fractionation of, 991  
—, in dye strippers, 993  
—, in lacquers, 993  
—, in pickling agents, 993  
—, in varnish remover, 993  
—, melting point of, 991  
—, molding of, 993  
—, preparation of, 991, 992  
Polyethylene succinate, properties of, 872  
Polyfunctional reactants, 1129  
Polyfurylethylene, preparation of, 243  
—, uses, 243  
Polyglycerol esters of rosin, in lacquers, 822  
Polyglycerol resin, properties of, 996  
—, viscosity of, 996  
Polyglycerols, as plasticizers, 896  
—, condensation of glycerols to, 795  
—, effect on rosin ester coatings, 796  
—, esterification with  $\alpha$ -pinene-maleate, 845  
—, rosin, 796  
—, preparation of, 995, 996  
—, reaction with polycarboxylic acids, 428  
—, rubbery product from, 996  
—, types of, 995  
—, use in alkyd resins, 864  
Polyglycidols, preparation of, 994  
Polyglycols, preparation, 895  
Polyhydric alcohol-carbohydrate resins, 760  
Polyhydric alcohol-cresoxyacetic-formaldehyde composition, 938  
Polyhydric alcohol esters, from tall oil, 756, 787  
—, reaction with sulphur chloride, 815  
Polyhydric alcohol mineral esters, action on cellulosic matter, 749  
Polyhydric alcohol-monobasic acid esters, modifiers, urea-aldehyde resins, 666  
Polyhydric alcohol-polybasic acid esters, modifiers, for urea-aldehyde resins, 665, 666, 668  
Polyhydric alcohols, alkyd resin from, 10  
—, as poly-functional derivatives, 862  
—, autocondensation, 896  
—, condensation with ketone-acids, 894  
—, condensation with oxidised glyceride oils, 1227  
—, cyclic ethers of, 839  
—, esterification agents for rosin, 792, 793, 795, 796, 797  
—, esterification of fossil resin-rosin mixture with, 811  
—, esterification with monobasic acids, 893  
—, polybasic acids, 892-875, 876, 895  
—, halogenated, modifiers, urea-aldehyde resins, 667  
Polyhydric alcohols, in vinyl resin manufacture, 1038  
—, modifiers, phenol-aldehyde resins, 427, 428, 429, 430  
—, preparation, 1062  
—, reaction with ether-carboxylic acids, 894  
—, reaction with titanium tetrachloride, 1239  
Polyhydric ester, of montan wax, 828  
Polyhydric phenols, reaction with aldehydes, 310, 311, 392  
Polyhydroxy acids, esterification with alcohols, 911  
—, preparation of, 910, 911  
—, use of, in alkyd resins, 910  
Polyhydroxy alcohols, esters from, 1224  
Polyhydroxy-carboxylic aliphatic acids, esterification of copal with, 810  
Polyhydroxy fatty acids, shellac substitutes from, 1006  
Polyhydroxy rubber compounds, 1093  
Polyindenes, character of, 58, 193, 104  
—, depolymerisation of, 104, 105  
—, diindene from, 104  
—, from indene, 100  
—, hexahydropolyindene from, 105  
—, hydrogenation of, 105  
—, injection molding of, 1324  
—, solubility of, 102  
—, unsaturation in, 100, 104  
—, use of, in lubricating oil, 200  
Polyisobutylene, compared with hydorrubber, 167  
—, effect of chemical reagents on, 166  
—, from isobutylene, 166  
—, physical properties of, 167  
—, solvents for, 166, 167  
Polyketones, formation of, 1000  
Polymer homologues, formation of, 72  
Polymeric acids, from polyacrylonitrile, 1075  
Polymeric adipic anhydride, structure of, 996  
Polymeric cis-anhydride, from cis-p-hexahydro-terephthalic acid, 999  
Polymeric carboxylic acids, use with polyacrylic acid derivatives, 1078  
Polymeric modifications, of ethyl acrylate, 1073  
Polymeric peroxides, from polystyrenes, 239  
Polymeric resins, examples of, 15  
Polymeric trimethylene carbonate, nature of, 870  
Polymerization, absence of lower polymers in, 48  
—, accelerated by irradiation, 547  
—, additive, definition of, 42  
—, of acetylene, 142  
—, of olefins, 164  
—, as unimolecular reaction, 49  
—, by glow discharge, 230  
—, by mercury light, 230  
—, catalysts for, 207, 258, 349  
—, catalytic, of styrene, 238-242  
—, chemical considerations of, 975  
—, classifications of, 42  
—, commercial, of allylene oxides, 992, 993  
—, definitions of, 42  
—, degree of, in urea resin, 587  
—, in vinyl ethers, 1011  
—, free radicals in, 48  
—, inhibition by groups, 46, 47  
—, mechanism, 48  
—, nature of, 48  
—, of acenaphthalene, 260  
—, of acetaldehyde, 496  
—, of acetylene, 142, 143, 144, 146, 147  
—, of acetylene homologues, 161, 162  
—, of acetylene polymers, 143, 144, 146  
—, of acrolein, 501, 502, 508, 504  
—, of acrylic acid, 1070-1073  
—, of acrylic acid derivatives, 1074, 1075  
—, of acrylidene-glycerol, 803  
—, of aldehyde-acids, 506  
—, of aldehydes, 505  
—, of aldols, 498, 499  
—, of anethole, 361  
—, of aromatic aldehydes, 507, 508, 509, 510, 511  
—, of atropic acid, 1084  
—, of benzaldehyde, 507, 508  
—, of o-bromostyrene, 259  
—, of bromostyrenes, 255  
—, of butadiene, 168, 178

Polymerisation, of butadiene derivatives, 169, 170, 171, 173, 1189  
 —, of butadiene homologues, 168, 169, 175, 179  
 —, of carbon suboxide, 1014, 1015  
 —, of cashew-shell oil, 1229  
 —, of cedrene, 783  
 —, of p-chlorostyrene, 259  
 —, of chloroprene, 155, 158, 157  
 —, of chloroprene homologues, 155, 159  
 —, of cinnamic acid, 1082-1084  
 —, of Congo resin, 811  
 —, of conjugated diolefins, 168, 169  
 —, of copal resins, 807, 808  
 —, of cracked distillates, 225-229  
 —, of cracked gasoline, 190-193, 199, 201  
 —, of crotonic acid, 1081  
 —, of C-stage phenol-formaldehyde resins, 290  
 —, of cumarone, 94, 95, 106, 107  
 —, of 1,3-cyclohexadiene, 167, 185, 183, 189  
 —, of cyclopentadiene, 185, 186, 187, 188, 256  
 —, of diacetylene, 162  
 —, of dichlorobutadiene, 170  
 —, of 1,3-dienes, 176, 180  
 —, of duodimethyldiphenylmethanes, 299  
 —, of dimethylbutadienes, 169, 172, 175, 176, 177, 179  
 —, of dimethylolurea, 581  
 —, of 2,4-dimethylstyrene, 259  
 —, of diolefins, 174, 175, 179, 184, 185  
 —, of asym-diphenylethylene, 59  
 —, of dipropargyl, 162  
 —, of divinylacetylene, 152, 153  
 —, of p-divinylbenzene, 241  
 —, of divinylhexenyne, 162  
 —, of electropolymerization products, 163  
 —, of eleostearic acid, 880  
 —, of emulsions, 245, 246  
 —, of p-ethoxy-propylbenzene, 258  
 —, of ethyl acrylate, 1073  
 —, of ethyl itaconate, 1085  
 —, of ethylene, 165  
 —, of ethylene oxide, 990-992  
 —, of p-ethylstyrene, 259  
 —, of eugenol, 280, 261, 262  
 —, of formaldehyde, 284, 330, 342, 394, 511-515, 757  
 —, in alkali solutions, 342, 343  
 —, of furfural, 518, 521  
 —, of furylbromomethylene, 243  
 —, of furylethylene, 243, 520, 522  
 —, of glycerol phthalate resins, x-ray studies in, 87  
 —, of glycidol, 994  
 —, of halogenated aldehydes, 506  
 —, of halogen-substituted vinylacetylenes, 160  
 —, of heavy acetylene, 144  
 —, of 1-heptyne, 161  
 —, of 1,5-hexadiyne, 162  
 —, of hydrogenated divinylacetylene, 154  
 —, vinylacetylene polymers, 160  
 —, of hydroxyaldehydes, 506, 507  
 —, of hydroxybenzyl alcohol, 349  
 —, of o-hydroxystyrene, 260  
 —, of indene, 95, 100, 104, 258  
 —, in carburetted water gas, 257  
 —, of isobutylene, 166, 167  
 —, of isoeugenol, 262  
 —, of isoprene, 169, 172, 173, 174, 175, 178, 179  
 —, of isoprene derivatives, 172  
 —, of isopropylbenzene, 258  
 —, of isosafrole, 261  
 —, of itaconic acid, 1085, 1086  
 —, of ketone-formaldehyde products, 663  
 —, of mercury-substituted vinylacetylenes, 160  
 —, of p-methoxy-propylbenzene, 258  
 —, of methoxystyrenes, 260  
 —, of methylacetylene, 161  
 —, of methyl acrylate, 1073, 1078  
 —, of methylcumarone, 94, 96  
 —, of 1-methyl-1,3-cyclohexadiene, 189  
 —, of methyleneurea, 678  
 —, of methyleneurethane, 682  
 —, of methylolurea, 578  
 —, of methylstyrenes, 257, 258  
 —, of methyl-substituted propargylphenyl ethers, 163  
 —, of methylvinylideneacetylene, 161

Polymerization, of monolefins, 225  
 —, of nitrostyrenes, 259  
 —, of 1-octyne, 162  
 —, of olefins, 164, 165, 167  
 —, catalysts for, 166, 176  
 —, effect of electric discharge, 164, 165  
 —, effect of temperature on, 164, 166  
 —, lubricating oils from, 166  
 —, of ozonides, 166  
 —, of paraformaldehyde, 516  
 —, of phenol-formaldehyde resins with ethylaliphonic acid, 320  
 —, of phenolphthalein, 1252  
 —, of phenolic resins, 358  
 —, x-ray studies in, 87  
 —, of phenolic styrenes, 260, 261, 262  
 —, of phenylbutadiene chloride, 1233  
 —, of 1-phenylpenta-4-ene-1-yne, 162  
 —, of phenylpropadiene, 155  
 —, of piperylene, 169  
 —, of propyl acrylate, 1073  
 —, of propylbenzene, 258  
 —, of regenerated rubber, 1116  
 —, of refining residues, 227  
 —, of safrole, 260, 261, 262  
 —, of styrene, 164, 232, 234, 235, 238, 239, 240, 241, 242, 243, 244, 246, 248, 249, 257  
 —, of styrene derivatives, 257, 258, 259, 260, 261, 262  
 —, of tall oil, 755  
 —, of thiofurfural, 338  
 —, of trimethylethylene, 167  
 —, of tung oil, 40, 401, 1215, 1216, 1217  
 —, of unsaturated hydrocarbons, 164, 216  
 —, of vinylacetylene, 150, 153  
 —, of vinyl-acetylene homologues, 160  
 —, of vinylacrylic acid, 1084  
 —, of vinyl derivatives of phenols, 260  
 —, of vinyl esters, 164, 166  
 —, of vinyl ethers, 164, 1010-1012  
 —, of vinyl ethinyl carbinols, 151  
 —, of vinyl halides, 164  
 —, of vinylhexenyne, 162  
 —, of vinylnaphthalene, 164, 243  
 —, of wood oils, 780  
 —, of wood tar, 751  
 —, premature, in urea resins, 619  
 —, relation to chemical structure, 43, 46  
 —, dipole moment, 45  
 —, reversible, of lactones, 1001  
 —, spontaneous, of cyclic anhydrides, 998  
 —, thermal, of isoprene, 170  
 —, of vinyl acetate, 1020  
 —, types of, 42  
 —, vectorial and crystallization, 30  
 Polymerization apparatus, description of, 179  
 Polymerization stages, in urea resin condensation, 586, 587  
 Polymerization tendency, of olefins, 168, 169, 170, 171  
 Polymerisation velocities, of butadiene derivatives, 169, 170, 171  
 Polymerized  $\beta$ -bromoacrylic acid, structure of, 1080  
 Polymerized carbon suboxide, structure of, 1014, 1015  
 Polymerized diolefins, in urea resin coatings, 637  
 Polymerized diphenylmethane, 299  
 Polymerized formaldehyde, molded insulation from, 264  
 Polymerized glycerol, 994  
 Polymerized hydrocarbons, added to lubricating oils, 227  
 Polymerized indene, bromine absorption of, 168  
 —, solubility of, 101  
 Polymerized isoprene, x-ray patterns of, 89  
 Polymerized lactams, formation of, 999  
 Polymerized petroleum distillates, chlorination of, 1187  
 Polymerized styrene, analogies to rubber, 62  
 Polymerized tung oil, with eumaron resin, 127, 128  
 Polymerizing oil, in cold-molding composition, 1298  
 Polymers, alternative polarity in chains of, 41  
 —, application of x-rays to, 76  
 —, behavior of films of, 40, 41  
 —, chain, irregular arrangement of units in, 174  
 —, dilute solutions of, nature, 76  
 —, effective volume of, 76

- Polymers, from benzyl chloride, 1129, 1180  
 —, from glycine, 66  
 —, from methylindenes, 105  
 —, large ring formation of, 58  
 —, molecular weight determination of, 73  
 —, of acrylic acid, 1073  
 —, of crotonic acid, 1081  
 —, of di-alcohol of diphenylmethane, 299  
 —, of ethyl acrylate, 1073  
 —, of ethylene, 184  
 —, of ethylene oxide, 993  
 —, of formaldehyde, condensation with thiourea, 617  
 —, —, condensation with urea, 616, 617, 623  
 —, —, in resin production, 326, 327  
 —, of styrene, classification, 234, 235  
 —, structure of, 55  
 —, three-dimensional, 59  
 —, types of, from butadiene and homologues, 170  
 —, vinyl, rosin in, 1047  
 Polymethacrylates, uses of, 1078, 1081  
 Polymethacrylic acid, properties of, 1080  
 Polymethylene polyesters, properties of, 872  
 Polymethylenes, reaction with halogens, 579  
 Polynaphthenes, oxidation of petroleum, 208, 209  
 Polynaphthenic acids, oxidation of petroleum, 208  
 Polymit, preparation of, 178  
 Polynuclear compounds, from phenol-formaldehyde reaction, 306  
 Polynuclear hydrocarbons, reaction with alkyl halides, 1131  
 Polynuclear phenol, modifier, phenol-aldehyde resin, 408  
 Polyolefins, chlorination of, 1158  
 Polyoxyethylene, phenol resins with, 331  
 —, x-ray studies, 56, 90, 91  
 $\alpha$ -Polyoxymethylene, from formaldehyde, 512  
 $\beta$ -Polyoxymethylene, from formaldehyde, 512  
 $\gamma$ -Polyoxymethylene, use of, 330  
 $\gamma$ -Polyoxymethylene, from formaldehyde, 513, 514  
 —, use of, 330  
 $\delta$ -Polyoxymethylene, from formaldehyde, 513, 514  
 $\epsilon$ -Polyoxymethylene, from formaldehyde, 513, 514  
 —, formation of, 578  
 Polyoxymethylene hydrate gel, x-ray pattern of, 91  
 Polypeptide chains, in muscle, 68  
 —, in wool, 68, 69  
 Polypeptides, nature of, 66, 67  
 Polyphenols, reaction with croton aldehyde, 392  
 Polyphenyls, production of, 1142  
 Polypropylene, cracking of, 259  
 —, 1,4-diphenylbutadiene from, 259  
 —, structure of, 258, 259  
 —, viscosity of, 258  
 Polypropylene oxides, properties of, 991  
 Polystyrene, formation in plants, 992  
 Polystyrene, analogies to rubber, 62  
 —, benzaldehyde from, 239  
 —, chain length of, 75  
 —, chlorinated as soldering flux, 247  
 —, chlorination of, 237  
 —, colloidal classification of, 235  
 —, coloring agents for, 237  
 —, depolymerization of, 234  
 —, 1,3-diphenylpropane from, 232  
 —, distyrene from, 232, 236  
 —, effect of acids, 241  
 —, — heat, 236, 238  
 —, — hydrofluoric acid, 237  
 —, — water, 237  
 —, extrusion molding of, 249, 250  
 —, from cracked petroleum, 254  
 —, hydrogenation of, 237  
 —, injection molding of, 250, 1523  
 —, isolation from solution, 242  
 —, isomer of, 1141  
 —, gelatinisation of, 234  
 —, glycerol-modified, 245  
 —, light-absorption of, 232, 233  
 —, nitration of, 237  
 —, physical properties of, 235, 236, 238, 239  
 —, plasticisers for, 237, 251  
 —, polymeric peroxides from, 238  
 Polystyrene, preparation of, 234, 238, 239, 240, 241, 242, 243  
 —, pyrolysis of, 232, 233  
 —, racking of, 62  
 —, Raman spectrum of, 232, 233  
 —, resistant to bromine, 234, 236, 237  
 —, solvents for, 58, 235, 236, 238  
 —, spongy masses from, 237  
 —, spraying lacquer from, 247  
 —, structure of, 58, 232-235  
 —, styrene from, 232, 236  
 —, sulphonation of, 237  
 —, 1,3,5-triphenylpentane from, 233  
 —, tristyrene from, 233  
 —, used as glass substitutes, 252  
 —, — impregnant, 248  
 —, — rubber plasticizer, 237  
 —, use in abrasives, 251  
 —, — antiparastic layers, 245  
 —, — coating compositions, 244, 246-251, 821, 943, 961  
 —, — color printing, 245  
 —, — dentures, 250  
 —, — dyeing, 245  
 —, — electrical insulation, 198, 245, 248, 249, 251  
 —, — germicides, 245  
 —, — laminated glass, 251, 252  
 —, — lubricants, 200, 249  
 —, — luminous paints, 247, 248  
 —, — oilcloth, 249  
 —, — vulcanization of, 195  
 Polystyrene emulsions, artificial latex from, 234  
 —, precipitation with methanol, 245  
 —, use in molding, 250  
 Polystyrene resin, use in sound recording, 248  
 Polystyrene solutions, streaming double refraction in, 70, 233  
 —, viscosity of, 73, 75, 235, 236  
 Polystyrenes, x-ray diffraction patterns of, 236  
 Polysulphides, modifiers for syntans, 420  
 Polyterpenes, from acetone-vinyl bromide reaction, 1253  
 Polythioformaldehyde, preparation, 1180  
 Polythiofurfural, preparation, 1181  
 Polythionates, as vulcanizing agents, 1206  
 Polyvalent phenol-formaldehyde resins, chemical resistance, 371  
 —, uses of, 371, 372  
 Polyvalent phenols, in urea-phenol-aldehyde resins, 677  
 —, reaction with aldehydes, 371, 372, 373  
 Polyvinyl acetal, of acrolein, 1061  
 —, of formaldehyde, 1061  
 Polyvinyl acetals, preparation, 1060, 1061, 1062  
 —, modifiers for, 1063, 1064  
 —, molding, 1062  
 —, use as celluloid substitutes, 1066  
 —, — sizing agents, 1058  
 —, use with cellulose acetate, 1063  
 —, — viscose, 1062, 1063  
 —, viscosity of, 1061  
 —, vulcanisation of, 1061  
 Polyvinyl acetate, effect of moisture, 1048  
 —, elastic properties, 1021  
 —, electrical insulators from, 1029  
 —, emulsions, 1027  
 —, gas-impermeable sheets from, 1078  
 —, hardening agent, acetaldehyde resins, 493  
 —, hydrolysis of, 1054, 1055, 1056, 1057, 1058, 1059  
 —, in adhesives, 1028, 1029  
 —, in artificial silk, 1030  
 —, in cellulose nitrate films, 1029  
 —, incorporation with lubricating oils, 1031  
 —, incorporation with manila copal, 1032  
 —, incorporation with phenol-formaldehyde resin, 1031  
 —, incorporation with rosin, 1032  
 —, in lacquers, 1025, 1027, 1033  
 —, in safety glass, 1023  
 —, intaglio ink from, 1027  
 —, preparation, 1059  
 —, purification of, 1024  
 —, reaction with organic acids, 1033  
 —, solubility behavior, 89, 1031, 1035  
 —, sound records from, 1060

- Polyvinyl acetate, specific viscosity of, 75  
 —, structure of, 53, 75, 1021  
 —, varnish from, 1032  
 —, x-ray examination, 1021  
 Polyvinyl acetate-chloroacetate, hydrolysis, 1057  
 Polyvinyl acetate-modified alkyd resins, 942  
 Polyvinyl acetate-oleate, reaction with butyraldehyde, 1062  
 Polyvinyl acetate-rubber, resistance to gasoline, 1030  
 Polyvinyl alcohol, acetals of, 1056, 1060, 1061, 1062  
 —, acylation of, 1055, 1057, 1059  
 —, alkylated, 1067  
 —, by hydrolysis of polyvinyl esters, 1069  
 —, colloidal properties, 1056  
 —, comparison with starch, 1054, 1055  
 —, effect of borax, 1053  
 —, — heat, 1066, 1059  
 —, — pressure, 1056  
 —, — tannin, 1059  
 —, ethers from, 1060  
 —, gels from, 1056  
 —, halogenated, 1056  
 —, lactic acid-modified, 1055  
 —, methyl ether of, 1055  
 —, modified, 1058  
 —, modifier in resin syntheses, 665  
 —, oxidation, 1056  
 —, polyvinyl acetate from, 1056  
 —, preparation, 1054, 1055, 1056, 1057, 1058  
 —, protective colloid, 1056  
 —, reaction with aldehydes, 565, 1056, 1058-1062  
 —, — alkylene oxides, 1060, 1067  
 —, — boron compounds, 1067  
 —, — carboxylated phenol-aldehyde resins, 427, 429  
 —, — chlorobenzene, 1059  
 —, — ethyl chloride, 1059  
 —, — halo-alkyl ethers, 1067, 1068  
 —, — ketones, 1063  
 —, — urea, 665  
 —, rubber-like material from, 1060  
 —, sheets of, 1056  
 —, solvents for, 1054, 1056  
 —, structure, 53, 1054, 1055  
 —, use with alkyd resins, 938  
 —, — cellulose esters, 1058  
 —, — foods, 1068  
 —, — safety glass, 1067  
 —, vulcanization of, 1056, 1060, 1207  
 —, water-resistance of, 1058, 1059  
 —, water solution of, 1067, 1058  
 Polyvinylammonium base, preparation, 1034  
 Polyvinylbenzene, co-polymerization with diolefins, 193  
 Polyvinyl bromide, properties, 1041  
 Polyvinyl butyrate, in safety glass, 1028  
 Polyvinyl butyrate, preparation, 1024, 1057, 1059  
 Polyvinyl chloride, celluloid substitute, 1037  
 —, chlorination of, 1043  
 —, effect of heat, 1048  
 —, — iron, 1048  
 —, evaluation, 1043, 1044  
 —, incorporation with alkyd resins, 1044  
 —, — phenol-formaldehyde resins, 1044  
 —, — rubber, 1043  
 —, in photographic films, 1043  
 —, in soldering flux, 1039  
 —, plastic masses from, 1038  
 —, properties, 1037  
 —, reaction with nitro aromatics, 1044  
 —, types of polymers, 1038  
 Polyvinyl chloroacetate, preparation, 1024, 1034  
 —, properties, 1024, 1034  
 —, uses, 1025, 1027, 1039  
 Polyvinyl citrate, from polyvinyl acetate, 1032  
 Polyvinyl compounds, hardening materials for acetaldehyde resins, 493  
 Polyvinyl compounds, reactions with aldehydes, 1029  
 Polyvinyl ester-acetals, moldings, 1062, 1066, 1067  
 —, preparation, 1065, 1066, 1067  
 —, uses, 1066, 1067  
 Polyvinyl esters, binders for metal powders, 1027  
 —, coating for cellophane, 1026  
 —, colloidal solutions of, 1037  
 Polyvinyl esters, combination with stand-oil extract, 1033  
 —, extruding, 1021  
 —, films from, 1029  
 —, hardening catalyst, 1029  
 —, hydrolysis, 1032, 1059, 1069  
 —, hydrolyzed, reaction with aldehydes, 1065, 1066, 1067  
 —, impregnation of wood pulp, 1030  
 —, in chlorinated rubber, 1033  
 —, in dyes, 1028  
 —, in safety glass, 963, 1016, 1067  
 —, in sizing agents, 1059  
 —, isobutyl phthalate with, 1028  
 —, mixed, 1026, 1057, 1059  
 —, modifiers, for phenol-resin varnishes, 445  
 —, molded products from, 1021, 1029  
 —, polyvinyl acetals from, 1061  
 —, properties, 1025  
 —, reaction with acetals, 1065  
 —, — boron compounds, 1023, 1057  
 —, — ethylidene diacetate, 1066  
 —, — ketones, 1063  
 —, resistance to acids, 1016  
 —, saponification, 1046  
 —, solubility, 1025  
 —, transmission of ultraviolet, 1025, 1052  
 —, use with Tekal, 1227

 Potassium persulphate, effect on chloroprene-rubber latex, 157, 158  
 —, oxidation of 3-hydroxybenzoic acid by, 375  
 Potassium phenate, reaction with monochlorodimethyl ether, 280  
 Potassium phosphate, hardening agent, urea-thiourea resins, 657  
 Potassium pyrosulphate, dehydrating agent,  $\beta$ -methylketobutanol, 550  
 Potassium resinate, from rosin, 770  
 —, use of, 355  
 Potassium salts, of symmetrical trihalogenated phenols, decomposition of, 379  
 Potassium stearate, use of, 355  
 Potassium succinate, reaction with vinyl chloride, 1019  
 Potassium sulphate, accelerator, gelatinization of urea-formaldehyde resins, 597  
 Potassium sulphide, reaction with ethylene dichloride, 1169  
 Potassium tetroxalate, hardening agent, thiourea resins, 654  
 Potassium thiocyanate, accelerator, gelatinization of urea-formaldehyde resins, 597  
 —, oils resinified by, 229  
 Potassium urea, preparation of, 571  
 Potassium zincate, resin purification with, 337  
 Potato flour, infusible products from, 700  
 Potentiometers, carbonized phenol resin in, 488  
 Potentiometric titration, acid numbers by, 1260  
 Pots, for centrifugal apparatus, from rubber, 1248  
 Pour point, of lubricating oil, improving, 200  
 Powder distempers, from urea resin, 631  
 Powdered charcoal, filler for phenol-aldehyde resin, 481  
 Powdered fillers, use of, 1275  
 Powdered metals, filler for phenol-aldehyde resin, 352  
 —, — sulphur castings, 1166  
 Powdered molding material, advantages of, 1320, 1321  
 —, preparation of, 1323  
 —, use of, 1321  
 Powdered stone, filler for phenol-aldehyde resin, 461  
 Powders, granulation of, 1319  
 —, molding of, 1296, 1320  
 Power-arc, tests for, 1347  
 Power factor, determination of, 1264, 1348, 1349, 1350, 1375  
 —, of alkyl-cemented mica, 932  
 —, variation with temperature, 1349  
 Po-yoak oil, botanical source of, 561  
 Precipitate, from acetaldehyde-phenol resin solutions, extraction of, 263

- Precipitated soaps, 784  
 Precipitation, in varnishes, 20, 35  
 —, of phenol-aldehyde resins, from hydrocarbon oils, 362  
 —, of resins, by acidification, 320, 321, 457  
 —, of resin by aluminum salts, 771  
 —, of urea resins, 635  
 —, of wood resins, 749  
 —, purification of phenol-aldehyde resins by, 337  
 Preparing, effect on molding properties, 612  
 Preforming, use of, 1317, 1318, 1319  
 —, volume reduction in, 1318  
 Preforming presses, types of, 1319  
 Preforms, adapting to inserts, 1319  
 —, advantages of, 1321  
 —, ball-shaped, use of, 1319, 1321, 1332  
 —, preheating of, 1321, 1322  
 —, shapes of, 1318  
 Preheater, use in continuous resin production, 334  
 Preheating, of molding material, 1321, 1322  
 Premature polymerization, of urea resins, 619  
 Preservation, of methyl rubber, 178  
 Preservative coating, cumarone resin in, 141  
 Preservative composition, 732  
 Preservatives, termite repellent, for test panels, 1368  
 Pressboard, from copal, 470  
 —, from shellac, 470  
 —, impregnation with resins, 1245  
 —, laminated, preparation of, 1282  
 —, oil-treated, dielectric strength of, 1348  
 —, phenol resins in, 470, 471  
 —, surfaced with synthetic resin, 1245, 1246  
 Presses, angle, construction of, 1307  
 —, arbor, for opening molds, 1321  
 —, automatic, operation of, 1312  
 —, cooling, use of, 1328, 1329

- , use, hardening phenol-aldehyde resins, 373
- , —, polymerization of 1,3-dienes, 180
- Pyrocatechol ethers, resins from, 714
- Pyrocatechol-formaldehyde resin, in water purification, 311
- Pyrocatechol-furfural reaction, resin from, 625

Pyrocatecholmonoacetic acid, condensation with formaldehyde, 378  
 Pyrogallic acid, action of air on alkaline solution of, 370  
 —, reaction with aldehyde-ammonia, 278  
 Pyrogallol, anticatalyst, polymerization of sulphones, 1178  
 —, antiseptic from, 277  
 —, bromination of, 1154  
 —, condensation with diphenylformamidine, 395  
 —, — paraform, 372  
 —, effect on chloroprene polymerization, 156  
 —, glyceride oils modified with, 1227  
 —, inhibitor, polymerization of styrene, 242  
 —, modifier, urea-aldehyde resins, 674  
 —, oxidation inhibitor, 501  
 —, reaction with acetylene, 383  
 —, — benzaldehyde, 277, 278  
 —, — crotonaldehyde, 392  
 —, — formaldehyde, 279, 280, 371  
 —, syntan from, 410  
 Pyrogallol-benzotrichloride condensation, 1135  
 Pyrogallol dimethyl ether, condensation with tiglic aldehyde and guaiacol, resin from, 280  
 Pyrogallol-furfural reaction, resin from, 525  
 Pyrogallol-paraform condensation, use in gum arabic, 372  
 Pyrogenous dissociation, of aromatic hydrocarbons, 270  
 Pyroligneous acid, absorption of vapors, 751  
 —, composition of, 751  
 —, dyes from, 751  
 —, methyl alcohol from, 751  
 —, reaction with phenols, 751  
 —, resins from, 751  
 —, sodium acetate from, 751  
 Pyrolusite, pigment, 1276  
 Pyrolysis, of aldehyde resins, 1068  
 —, of cumarin, 94  
 —, of chloroethylbenzene, 252  
 —, of 1,3,5-dimethylethylbenzene, 253  
 —, of ethylbenzene, styrene from, 242, 253, 254  
 —, of ethylnaphthalene, 254  
 —, of natural gas, 96  
 —, of olefins, 164  
 —, of polystyrene, 232  
 —, of vinyl resins, 1068  
 —, of xylene, styrene from, 253  
 Pyrolytic products, of acetylene, 256  
 —, of acrylic acid, 1072  
 —, of styrene, 232  
 Pyruvic acid, modifier, phenol-aldehyde resins, 439  
 Pyrones, catalyst, formaldehyde polymerization, 512  
 Pyrotechnics, metallic soaps in, 791  
 Pyroxylin, as adhesive, 989  
 —, in coating compositions, 663, 965  
 —, incorporated with nitro resins, 729  
 —, in rubber coating composition, 1092  
 —, ketone resins, coating compositions, 549  
 —, use with vinyl ethylcarbinol polymer, 151  
 Pyroxylin lacquers, cumarone resin as substitute for, 129  
 —, destructively-distilled castor oil condensation product in, 826  
 —, ester gum in, 826  
 Pyroxylin plastic compositions, non-discoloring, effect of alkyl resins, 977  
 Pyroxylin plastics, production of, 12  
 Pyroxylin-resin mixtures, solvents for, 31  
 Pyrrole, condensation with acetaldehyde, 741  
 —, — acetone, 541  
 —, — aniline, 741  
 —, — formaldehyde, 741  
 —, — methylcyclohexanones, 741  
 —, — methylethyl ketone, 741  
 —, —  $\alpha$ -naphthylamine, 741  
 —, — oxalyl chloride, 742  
 —, — phenylethyl ketone, 741  
 —, oxidation, resin formation, 740  
 —, reaction with formic acid, 740  
 —, — hydrochloric acid, 740  
 —, — maleic anhydride, 847  
 —, — triphenylmethyl, 847

Pyrrole, tripyrrole from, 740  
 Pyrrole blacks, 740  
 Pyrrole-N-carboxylic acid, resinification, 740  
 Pyrrole derivatives, condensation with aromatic aldehydes, 741  
 Pyrrole-2,5-dipropionic acid, formation of, 847, 848  
 Pyrrole- $\alpha$ -ketomethylcarbinol, resinification by, hydrotic acid, 742  
 Pyrrole red, from pyrrole, 740  
 Pyrrole resin, light sensitivity of, 689  
 Pyrrolidine, condensation with formaldehyde, 741  
 1,2-Pyrrolidone-5-carboxyanilide, preparation, 690  
 Pyrrolidinetomethyl alcohol preparation, 741  
 Pyruvic acid, condensation with aniline, 690  
 —, — benzaldehyde, 542  
 —, — formaldehyde, 542  
 —, Dobner's reaction, 690  
 —, from  $\beta$ -bromoacrylic acid, 1080  
 —, polymerization, 542  
 —, sodium salt, reaction with hydrogen, 542

## Q

Quantitative tests, for resins, 1260  
 Quartz, powdered, aqueous suspensions of, 32  
 —, —, use of, 450, 477, 960  
 —, use in chlororubber paint, 1125  
 Quartz lamps, discoloration tests with, 1378  
 —, transformation of isoprene sulphone with light from, 172  
 Quebrachamine, resins from, 745  
 Quebrachitol, esterifying agent, 1233  
 —, use with alkyl resins, 924  
 Quebracotannin-formaldehyde resin, for water purification, 311  
 Quick-drying paints, 975  
 —, varnishes, 1365  
 Quicklime, use in chlorinated rubber paints, 1125  
 —, catalyst, for rosin esterification, 794  
 —, —, phenol-formaldehyde reaction, 281, 343  
 Quinine, reaction with carbon suboxide, 1015  
 —, reaction with polyacrylic acid, 1072  
 Quinine sulphate, gels from, 38  
 Quinine-amine derivatives, resinification of, 745  
 Quinine-amine phthalate, resins from, 1254  
 Quinoidal nature, of maleic anhydride, 831  
 Quinol, bromination of, 1154  
 —, condensation with formaldehyde, 371  
 —, modifier, urea-aldehyde resins, 674  
 —, oxidation inhibitor, 501  
 Quinoline, condensation with epichlorohydrin, 739  
 —, reaction with barium oxide, 739  
 —, reaction with lignite, 275  
 —, reduction, resin formation, 739  
 Quinoline- $\gamma$ -carboxylic acids, from pyruvic acid, 690  
 Quinoline-sulphur system, 1160  
 $\beta$ -2-Quinolylpropane- $\alpha$ - $\gamma$ -diol, alkyl resins from, 904  
 Quinone, from acetylene and carbon monoxide, 161  
 —, from phenanthrene, 269  
 —, reaction with ammonia, 561  
 Quinone imines, polymerisation, 739  
 Quinones, as hardening agents, 358  
 —, effect on chloroprene polymerization, 156  
 —, polynuclear, 1140  
 —, reaction with cyclopentadiene, 830, 831  
 —, reaction with diazomethane, 832  
 —, reaction with methyleneanthrone, 834  
 Quinotoxineoxime, resinification of, 745

## R

Radio cabinets, molding of, 1267, 1300, 1332  
 Radio parts, from rubber, 1088  
 Radio transformers, mounting of, 1313  
 Radio-tube bases, molding, 1332  
 Radium emanations, effect on phenol-aldehyde resins, 434, 438  
 Radon, use in acetylene polymerisation, 144  
 Rag filler, phenol-aldehyde resins, 865  
 Railroad ties, impregnants for, 1155  
 Raman spectra, polystyrene, 232, 233  
 —, silicic acid esters, 1236  
 Ramie, study of, by Spierer lens, 64

- Ramified chain structure, urea resin, 581, 583  
 Rancidification of oils, prevention of, 909  
 Rapeseed oil, combination with olefin-sulphides, 1171  
 —, reaction with acetone, 541  
 —, with chlororubber, 1124  
 Rapeseed oil acids, lacquer substitutes from, 803  
 —, use in alkyd resins, 662, 984  
 Rare earths, oxidation catalysts, 497  
 Rate of absorption in laminated materials, 1343  
 Rate of condensation, of phenols, 847  
 Rate of polymerization, of acrylic acid, 1071  
 —, cumarone, 118  
 —, ethylene oxide, 991  
 —, itaconic acid esters, 1085  
 —, styrene, 235  
 Rayon, dyang, use of cellulose-modified syntans, 421, 422  
 —, resins incorporated, 548, 639  
 $\alpha$ -Rays, effect on olefins, 164, 165  
 —, effect on vinylacetylene, 149  
 —, polymerization of acetylene, 144  
 $\gamma$ -Rays, polymerization of acetylene, 144  
 Reaction control, in continuous processes, 334  
 —, in one-stage wet process for resins, 322  
 Reaction rate, rosin esterification, 794, 795  
 Reaction-time, effect in acetylene polymerization, 145  
 —, effect of hydrogen ion concentration, 612  
 —, effect on polymers of allyl cinnamate, 1083  
 Reactivity of phenols, effect of substituents on, 366, 367  
 —, order of, 347  
 Rearrangement of eleostearic acid, 858  
 Reciprocating pumps for hydraulic press, 1308  
 Recording instruments on presses, 1312  
 Recovery of glycerol, 994  
 Recovery of resins from waste liquor, 754  
 —, from wood, 749  
 Reducing agents, use in polymerization of 1,3-dienes, 180, 181  
 Reduction, benzene, resin formation in, 268  
 —,  $\beta,\beta$ -dihydroxydinaphthylmethane, 270  
 —, indene, 97  
 —, vinylacetylene polymers, 160  
 Reductone, polymerization, 539  
 Reeds, impregnated, artificial wood, 1245  
 Refining, chloronaphthalene waxes, 1152  
 —, coal-tar fractions, 108, 361  
 —, lubricating oils, 227  
 —, naphtha, 227  
 —, phenols, 319  
 —, vapor-phase, cracked gasoline, 226  
 Refining residues, polymerization of, 227, 228  
 Refraction, polystyrene solutions, 233  
 Refractive index, phenol-formaldehyde resin, 312  
 —, in polymerization studies, 50, 312  
 —, phthalate resins, 957  
 —, polymerized indene, 103  
 —, polystyrene, 236  
 —, resins, 1258, 1262  
 Refractory articles, from synthetic resins, 1250  
 Refractory materials, cold molded, 1317  
 Refrigeration, in rosin purification, 768  
 Refrigerator linings, alkyd resins in, 964  
 Regenerated cellulose, Aroclor resins in, 1150  
 Regenerated cellulose films, effect of sulphonamide-aldehyde resin, on 721  
 Reimer-Tiemann reaction, velocity of, 366  
 —, formation of resin, 299  
 "Reinforced" oil, from vegetable drying oil, 1233  
 Reinforcement for ceramic articles, urea-aldehyde resin, 685  
 Rejects, remolding of, 1332  
 Relationships, diagrammatical, among alkyd resins, 874  
 Relative humidity, in testing laminated materials, 1344  
 Relative viscosity, determination of, 74  
 —, relation to specific, 74  
 Relief prints from vinyl resins, 1033  
 Remolding of flash, 1321, 1332  
 —, rejects, 1333  
 Resins, molding of, 1925  
 Repairs of molds, 1364  
 Resene, influence in rosin, 764, 765  
 —, separation from rosin, 766  
 Residues, glycerol distillation, 994  
 —, waste liquor fermentation, 754  
 Resin acids, from waste liquor, 753  
 —, in tall oil, 755  
 —, modifiers, phenol-aldehyde resins, 437  
 —, reaction with hydroxyalkyl esters of drying oil acids, 803  
 —, — phenol compounds, 793  
 —, — ricinoleic acid, 803  
 Resinamines, character of, 276  
 Resinate driers, action of, 784, 976  
 Resinates, amino alcohols, 827  
 —, from waste liquor, 753  
 —, in limed rosin, 771, 783  
 —, reaction with glycerol, 794  
 —, stabilizers, vinyl resins, 1048  
 Resinene, character of, 275  
 —, mellitic acid from, 276  
 Resin esters, modifiers, phenol-aldehyde resins, 337, 400  
 —, reaction with boron trifluoride, 804  
 —, use in carbon paper, 827  
 —, use in cellulose lacquers, 822  
 —, use in solubilizing pitches, 1251  
 Resin formation, condensation, 862  
 —, nature of, 42, 44  
 —, use of molecular still in, 872  
 Resin glycerides, from linseed oil with metallic resinates, 803  
 —, use in tung oil coatings, 1216  
 Resinic acids, action of sulphonic acid chlorides on, 1206  
 —, reaction with aromatic sulphonylchlorides, 723  
 —, reaction with drying oil acids, 803  
 Resinification, control of, by modifying agents, 10  
 —, formation of solid solutions in, 44  
 —, physical aspects of, 43, 44  
 Resin-nitrocellulose films, properties of, 822, 826  
 Resinogen, definition of, 45  
 Resinoic acid, properties of, 276  
 Resinoids, definition of, 14, 291  
 —, structure of, 291  
 Resin oils, plasticizers, polystyrene, 247  
 Resinolic acids, definition of, 1007  
 —, chlorination of, 1006  
 Resinols, phenolic, from tar, 275  
 —, properties of, 276  
 —, shellac substitutes from, 1189  
 Resinophore groups, 45, 562  
 Resinotannol esters, composition of, 1193  
 Resinotannol-formaldehyde resins, 700  
 Resinous state, nature of, 27  
 Resin production, continuous processes for, 334, 335  
 Resin-pyroxylin mixtures, choice of solvents for, 39  
 Resins, acid numbers, 1256, 1260  
 —, analogies to rubber, 62  
 —, analytical methods, 1256  
 —, ash tests, 1261  
 —, by three-stage condensation, 353  
 —, classification of, 14  
 —, colloidal phenomena in, 36-41, 1263  
 —, colloidal solutions, stabilising of, 1251  
 —, color tests, 1259, 1262  
 —, convertible by heat, nature of, 868  
 —, decoration of, 1333, 1334  
 —, definition of, 11, 12  
 —, density determinations, 1258, 1262  
 —, differentiation of natural from synthetic, 310  
 —, double refraction, 1262  
 —, electrical properties, 1255  
 —, electrical tests, 1256, 1264, 1266  
 —, extrusion of, 1323  
 —, fluorescence, 1263  
 —, fossil, 18, 19  
 —, hardness of, 60, 61  
 —, heat-hardening *in situ*, 1245  
 —, identification methods, 1256  
 —, in photography, 741  
 —, liquid, use as adhesives, 1246  
 —, melting points, 1263, 1264

- Resins,  $\alpha$ -mesomorphic state, 62**  
 —, metallic coatings on, 1251  
 —, natural, *see* natural resins  
 —, nature of, 63  
 —, non-convertible by heat, 863  
 —, optical properties, 1262  
 —, physical tests, 1256, 1264  
 —, plasticizers, chlororubber, 1119, 1123  
 —, purification by adsorption, 336  
 —, quantitative tests, 1260  
 —, refractive index, 1258, 1262  
 —, relation to glass, 29  
 —, relation to rubber-like substances, 1087  
 —, saponifiable, use with cumarone resin, 139  
 —, saponification numbers, 1260  
 —, softening interval in, 29  
 —, softening points, 1263, 1264  
 —, solubility tests, 1261  
 —, structure of, 33, 34, 63  
 —, synthetic, miscellaneous uses for, 1243-1251  
 —, temperature effects, 1263  
 —, thermosetting, flow of, 1329  
 —, transparency to ultraviolet, 1263  
 —, viscosity, 1264  
 —, x-ray study, 76, 79, 1263  
**Resin samples, purification, 1258**  
**Resin scrap, recovery, 629**  
**Resin soaps, from wood, 753**  
**Resin varnishes, comparison with cellulose lacquers, 822**  
**Resistance, Aroclor varnishes, 1146**  
 —, electrical, of synthetic resins, 476, 367, 868, 1250  
 —, water, of phenol-carbohydrate resins, 760  
**Resistance wires, imbedded in molding, 1334**  
**Resistivity, electrical, tests for, 1350**  
 —, varnishes, effect of humidity, 1374, 1375  
 —, varnishes, tests for, 1373-1375  
**Resists, from polyvinyl alcohol, 1057**  
**Resites, branched-chain macromolecules, 307**  
 —, condensation with dihydroxybiphenyl, 408  
 —, conversion of resitols to, 444  
 —, definition of, 315  
**Resitols, conversion to resites, 444**  
 —, definition of, 307, 315  
**Resoglas, polystyrene, 232, 961, 1119**  
**Resoline, preparation of, 1223**  
**Resols, composition of, 307**  
 —, condensation with tung oil, 405  
 —, conversion to resitols, 444  
 —, definition of, 306, 315  
 —, spirit-varnishes from, 443, 444  
**Resolving agents, use of alkyl resins as, 907**  
**Resonic acid from tars, 275**  
**Resorcinol, action on chitin acetate, 1255**  
 —, antiseptic from, 277  
 —, color reactions, 1259  
 —, condensation with castor oil, 406  
 —, cyclohexanone, 560  
 —, 2,7-N-diacetyldiaminodiphenic anhydride, 732  
 —, paraformaldehyde, 371, 373, 405  
 —, paraldehyde, tung oil monoglyceride, 405  
 —, effect in phenol-aldehyde resins, 373  
 —, esterification with copals, 810  
 —, in purification of rosin, 765  
 —, molded products from, 465  
 —, reaction with acetaldehyde, 278  
 —, acetone, 373, 387  
 —, acetylene, 256, 383  
 —, benzaldehyde, 277, 278  
 —, benzoyle cyanide, 373, 737  
 —, benzylidenacetophenone and chloranil, 295  
 —, crotonaldehyde, 392  
 —, diphenic anhydride, 391  
 —, diphenylformamidide, 394  
 —, ethyl cyclohexanonecarboxylate, 391  
 —, formaldehyde, 279, 343, 371, 372, 690, 941  
 —, hexamine, 310

 —, polymerized 2,6-dimethyl-1,5-cyclooctadiene, 1088  
 —, sulphurized oils, 1204  
 —, Toron, 1199  
 —, urea resin, 589  
 —, vinyl ester-aldehyde resins, 1065  
 —, vulcanised polyvinyl alcohol, 1207  
 Rubber-sulphonic acid products, 1097-1100  
 Rubber-sulphonic compounds, "Thermoprene" from, 1099  
 Rubber-sulphuric acid products, 1097-1100

Rubber tetrabromide, reaction, with phenol, 1114  
 —, preparation, 1114  
 Rubber threads, preparation of, 1101  
 Rubber tiles, bonding to wheels, 1247  
 Rubber tires, cumarone resin in, 132  
 Rubber undercoatings, for cellulose esters, 1099  
 Rubber vulcanization, use of amine-aldehyde products, 435  
 —, use of aniline-sulphur chloride product, 1194  
 —, use of chloronaphthalenes, 1152  
 —, use of selenium sulphide, 1163  
 Rubber-vulcanisation molds, from phenol-aldehyde molding powders, 459  
 Rubbone, drying resin, 1093  
 Rubrene, preparation of, 269  
 —, resin from, 269  
 Rue, oil of, resin from, 1253  
 Rupture, modulus of, determination of, 1342  
 Russian peat, resins from, 274  
 Russian turpentine, modifier, phenol-aldehyde resins, 419  
 Rust-preventing paints, alkyl resins in, 976  
 —, chlorinated rubber in, 1121  
 —, ester gum in, 818  
 —, preparation of, 915  
 —, sulphurized oil in, 1208  
 Rust removers, cumarone resin in, 141  
 Ruthenium chloride, reaction with phenol resins, 310

## S

Sabinol, derivatives of, 733  
 Saccharides, condensation with amines, 710, 757  
 Saccharification, of peat, 749  
 Saccharin, catalyst, polymerization of methylolurea, 613  
 —, preparation of, 712, 713  
 Safety glass, preparation of, 1233  
 —, use of alkyl-chlorinated biphenyl composition, 944  
 —, — Aroclors in, 1150  
 —, — castor oil, maleic anhydride and 1,3-butylene glycol product, 855  
 —, — cellulose derivatives in, 490  
 —, — chlororubber, 1126  
 —, — ester gum, 827  
 —, — factice in, 1212  
 —, — gelatin-modified alkyl resins in, 944  
 —, — hydorrubber, 1096  
 —, — phenol-formaldehyde resin, 434, 435  
 —, — polymerised phenylacrylic acid esters in, 1083  
 —, — sulphamide-aldehyde resins in, 718, 719  
 —, — terpinene derivatives, 733, 844  
 —, — urea resins, 434, 639  
 —, — vinyl resins in, 1016, 1028, 1051  
 Saffrole, polymerisation of, 260-262  
 Salicylactic acid, 883, 894  
 Salicylaldehyde, condensation with 4,6-dinitro-m-xylene, 726, 741  
 —, modifier, syntans, 421  
 —, reaction with acetylbenzoyl, 551  
 —, — butyrylacetophenone, 557  
 —, — phenol, 278  
 —, — propionylacetone, 557  
 —, resinification of, 510, 1133  
 Salicylates, modifiers, urea-aldehyde resins, 678  
 Salicylic acid, anhydrides of, 375  
 —, catalyst, darkening resins, 1244  
 —, film-hardening agent, 633  
 —, in acetaldehyde resins, 492  
 —, in alkyl resins, 911, 936, 981  
 —, in carbohydrate resins, 758  
 —, in driers, 787  
 —, in linseed oil paint, 976  
 —, in phenol-aldehyde resins, 439  
 —, in urea-formaldehyde condensation, 610, 663, 678  
 —, preparation of, 374  
 —, reaction with amines and aldehydes, 707  
 —, — aralkyl halides, 1133  
 —, — benzaldehyde, 374  
 —, — formaldehyde, 374, 383  
 —, — gallic acid, 377  
 —, — hexamethylenetetramine, 309, 375

Salicylic acid, reaction with mercuric oxide, 375  
 —, — phosgene, 375  
 —, — rosin, 803  
 —, reduction with sodium amalgam, 277  
 —, saliretin from, 277  
 Salicylic esters, phenol-aldehyde resins, solubility, 422  
 Salicylic-sulphonated ricinoleic acid-formaldehyde resin, use, 420  
 Saligenin, reactions of, 281, 282, 283, 292, 294, 296-298, 299, 301  
 —, preparation of, 281  
 —, relation to Novolak, 309  
 —, resins from, 287, 310, 332, 479  
 —, saliretone from, 282, 291  
 Saliretasine, preparation and properties of, 282, 283  
 Saliretins, nature of, 291  
 —, preparation of, 277, 281, 282, 291, 292, 299  
 Saliretin-type resins, from cresols, 367  
 Saliretone, preparation and properties of, 282  
 Salol, melts, nature of, 29, 30  
 Salt-linkages in wool, 68, 69  
 Salt water, tests for varnishes, 753, 1368  
 Salts, as aggregators, 69  
 —, as anti-foaming agents, 353  
 —, in amine-aldehyde resins, 696  
 —, in aniline-formaldehyde condensation, 695  
 —, in glycerol resinification, 423  
 —, in light-fast resin solutions, 1250  
 —, in phenol-formaldehyde condensation, 352-357  
 —, in styrene polymerization, 242  
 —, in urea-aldehyde condensation, 590, 593, 594, 610, 621, 623  
 —, of alkyl resins, 945  
 —, of castor oil-phthalic acid, 909  
 —, of styrene-maleic anhydride, 244, 245  
 —, preparation in gelatinous form, 30, 31  
 Sand, abrasion resistance tests for varnish with, 1366  
 —, as filler, 349, 352, 480, 481, 1165, 1166  
 Sandal-seed oil, factice from, 1212  
 —, polymerisation, 1233  
 Sandarac, in phenol-aldehyde resin, 358, 426  
 —, in urea resin lacquer, 632  
 Sandarac gums, esterification of, 814  
 Sanding sealers, production of, 912  
 Sandpaper, use of alkyl resins in, 996  
 —, waterproof, preparation, 1248  
 Sandpaper belts, use, finishing moldings, 1331  
 Santolites, compatibility with cellulose acetate, 966  
 Saponification numbers, resins, 1260  
 Saponin, use as protective colloid, 245, 326  
 Sapropel, formolites from, 213  
 Satin-like finish, sheet material, 1325  
 Sawdust, in amine-aldehyde resins, 692, 696  
 —, in cold-molding composition, 1287  
 —, in linoleum, 193  
 —, in phenol-aldehyde resins, 373, 373  
 —, in sulphur castings, 1166  
 —, in tar acid-aldehyde resins, 361  
 —, resin from, 748, 749  
 —, resin purification with, 333, 339  
 Schiff's bases, 633  
 Schuit, use in bearings, 461, 496  
 Schultz's base, 639  
 Seorch-retarders, 789, 985  
 Seorching, of chloroprene-rubber compounds, 159  
 Scrap resin, conversion of, 340  
 —, recovery of, 629  
 —, remolding of, 1335-1338  
 Scrap rubber, utilization of, 1091  
 Scratch hardness tests, for laminated materials, 1351  
 —, for varnishes, 1371, 1372  
 Screen analysis, of molding materials, 1357  
 Screen, coating with butadiene polymer, 199  
 Screw inserts, for moldings, 496  
 Screws, of synthetic resins, 1248  
 S. D. O. definition of, 183  
 Sealing, with resins, 1313  
 Sealing compositions, from phenol-aldehyde resins, 424  
 —, from sulphur, 1166  
 —, from sulphur and cumarone resin, 1163

- Sealing wax, amine-aldehyde resin, 700  
 —, biphenyl resins in, 1150  
 —, chloronaphthalene in, 1153  
 —, naphthalene-formaldehyde resins in, 264  
 Sea water, coating, resistant to, 1245  
 —, effect on cumarone resin paints, 129  
 —, chlorinated-rubber paint, 1123  
 Sebacic acid, condensation with ethylene glycol, 892, 999  
 —, — glycerol, 892  
 —, in alkyl resins, 883, 892, 908, 936, 937, 941, 963  
 —, in Teglaes, 915  
 Sebacic aldehyde, polymerization of, 507  
 Sebacic polyanhydride, preparation of, 996, 997  
 Secondary valence and gelation, 39, 975  
 Secondary valence forces, in alkyl resins, 869  
 Sedimentary rocks, catalyst, polymerization, 226  
 Seeding, nature of, in varnish films, 36  
 Seed-lac, nature of, 23  
 Selenous acid, reaction with castor oil, 1223  
 Selenium, in electrical insulation, 1163  
 —, in fireproofing compounds, 1147  
 —, in tung oil, use, 1209, 1217  
 —, in varnish making, 1205  
 —, modifications, 1180  
 —, reaction with dextrin, 1168  
 —, — phenols, 1193  
 —, — rosin-maleic adduct, 856  
 —, — sulphur, 1163, 1188  
 Selenium chloride, reaction with phenol resins, 310  
 Selenium oxychloride, reaction with phenol, 1193  
 Selenium sulphide, properties, 1163  
 Selenium tetrachloride, reaction with ethyl malonate, 1241  
 Selenobenzaldehyde polymers, 1180  
 Selenoglycerols, 1177  
 Selenonium chloride, preparation and properties of, 1193  
 Self-lubricating bearings, preparation of, 460  
 Self-lubricating gears, manufacture of, 473  
 Semi-automatic presses, 1312  
 Semi-drying alkyl resins, 874, 875  
 Semi-drying oils, chlorinated, use, rubber compounding, 1127  
 —, from Gilsonite, 274  
 —, oxidation of, 1225  
 Semi-rotten wood, examination of, 64  
 Sensitizer, for phenol resins, 453  
 Separators, for electrical accumulators, 485  
 Serrinol, from silk, 68  
 Sesame oil, with cumarone resin, 135  
 Sesquiterpenes, formation of, 1099  
 Setting-time, of molding material, 1358  
 —, of varnishes, 1362  
 Shale oil, extraction of phenols from, 364  
 Shape, of molded material, influence of, 1320, 1321, 1325  
 —, of preforms, 1318  
 Shark-liver oil, paint from, 1209  
 Shatterproof glass, *see* Safety glass.  
 Shearing stress, nature of, 34  
 Sheetting, of phenol-formaldehyde resins, 432  
 Sheet metal, decorating, use of resins, 1247  
 Sheets, extrusion of, 1323  
 —, of alkyl resins, 873  
 —, molding of, 1320  
 —, perforated, preparation, 1334  
 Sheet-stock, preparation of, 1290  
 Sheet-stock molds, operation of, 1296  
 Shelf driers, use of, 1230  
 Shellac, and alkyl resins, comparison of, 905  
 Shellac, artificial, 210, 1004-1007, 1097  
 —, compatibility with nitrocellulose, 24  
 —, esterification of, 813  
 —, for sheet veneer, 447  
 —, from composite resins, 1032  
 —, hardening of, 703, 708, 1296  
 —, incorporation into alkyl resins, 918, 916, 917, 943, 948, 963, 983  
 —, in electrical insulators, 986  
 —, in mica compositions, 982, 983, 1274  
 —, in molding compositions, 983  
 —, in sound records, 24, 476, 983, 1335-1338  
 —, use with cumarone resin, 134, 135  
 —, — phenol-aldehyde resins, 415, 426, 486  
 Shellac, use with rosin, 777, 813  
 —, molding of, 1288, 1287, 1314, 1815, 1317, 1327, 1331, 1335  
 —, origin of, 12  
 —, plasticity of, 32  
 —, pressboard from, 470  
 —, production of, 18  
 —, properties and nature of, 23-25, 1000, 1004-1006  
 —, reaction with ethylene oxide, 993  
 —, reconditioned, 778  
 —, solvents for, 1228  
 —, sulphurization of, 1206  
 Shellac-bonded sheets, phenolic-resin veneers for, 476  
 Shellac-like resins, preparation of, 266, 347, 778, 914, 1006, 1099  
 Shellac substitute, from alkyl resins, 902  
 —, from benzyl chloride, 1130  
 —, from cashew-shell oil, 1230  
 —, from fatty acids, 1139  
 —, from phenol alcohol resins, 287  
 —, from phenol-aldehyde resin, 284, 330, 331, 364, 367, 369, 417, 432  
 —, from phenol-sulphur chloride resin, 1188  
 —, from rosin, 775, 803  
 —, from rubber, 1093, 1097, 1100, 1101  
 —, from vinyl resins, 1065, 1067  
 —, in record manufacture, 1335  
 Shellediolcarboxylic acid, structure of, 1005  
 Shellolic acid, isolation and properties of, 1004-1006  
 Ships, coatings for, 154, 1126, 1248  
 Shock-insulating medium, cumarone resin in, 136  
 Shock-resistance, molded products, 1269  
 Shoe filler, coal tar bitumen in, 360  
 Shoe lining, cloth, cumarone resin in, 138  
 Shoe-upper stiffener, ester gum in, 829  
 Shore elasticity, of cured flexible alkyl resins, 873  
 Shore hardness, of cured flexible alkyl resins, 873  
 Short-drying alkyl resins, properties of, 874  
 Short oil varnish, defined, 801  
 —, from Albertol-tung oil, 402  
 —, from Aroclors, 1146  
 —, from cumarone resin, 125, 128, 129  
 Short-time test, for dielectric strength, 1345  
 Shrinkage, of moldings, 249, 606, 1299  
 Shrinking of textiles, effect of resins, 639  
 Siberian fir oil, 782  
 Siccative alkyl resins, rosin in, 931, 932, 933  
 Siccatives, preparation of, 207, 412, 953  
 Sienna, pigment, 1276  
 Signal devices, on presses, 1312  
 Silent electric discharge, use as catalyst, 143, 161, 162, 165, 335, 806, 1013  
 Silica, filler, 1126, 1275  
 Silica, plastics from, 32  
 Silica black, preparation and uses of, 1235  
 Silica gel, action on glyceride oils, 1227  
 —, mazout, 203  
 —, — ozocerite, 203  
 —, as xerogel, 37  
 —, catalyst, alkylation of aniline, 704  
 —, — ammonia-rosin reaction, 804  
 —, — polymerization, 185, 226, 991  
 —, — styrene separation, 254  
 —, extractant, petroleum resins, 203  
 —, preparation of, 1235, 1236  
 —, properties of, 1235  
 Siliceous earth, in rosin oil manufacture, 779  
 Silicic acid, in diene rubber, 195  
 Silicic acid esters, gelling of, 1235  
 —, Ramon spectra for, 1236  
 —, reactions of, 1237  
 Silicic acid gels, nature of, 37, 1235  
 Silicon dioxide, as filler, 450, 633, 961, 962, 1147, 1166, 1359, 1359  
 —, gelatinisation of, 1235  
 —, in rubber purification, 176  
 —, reaction with coal, 1235  
 Silicon carbide, in shock-resistant coatings, 1248  
 Silicon esters, nature and uses of, 1286, 1337  
 Silicon ester paints, preparation and properties of, 1235-1237  
 Silicon resins, nature of, 1235, 1289

- Silicon tetrachloride, alkyl orthosilicates from, 1236-1238  
 —, reaction with linseed oil, 1239  
 Silicotungstic acid, in alkylid resins, 980  
 Silk, artificial, creasing, 639  
 —, —, from alkylid resins, 873, 965  
 —, —, from polyesters, 1000  
 —, —, from styrene, emulsions, 246  
 —, —, from synthetic resins, 1244  
 —, —, from urea and formaldehyde, 647  
 —, as a mesomorphic state, 62  
 —, as xerogel, 37

 Sodium acetate, condensing agent, 735  
 —, in glycerol polymerization, 796, 995  
 —, in phenol-aldehyde condensation, 281, 343, 415  
 —, in rosin esterification, 795  
 —, in urea-aldehyde resins, 581, 590, 593, 597, 657, 658  
 —, preparation of, 751  
 Sodium-acetone-bisulphite, as hardening agent, 392, 759  
 Sodium acetylde, reaction with alkyl iodide, 162  
 Sodium acid phosphate, catalyst, for ethylene-carbon dioxide reaction, 1070  
 Sodium acid sulphide, reaction with ethylene chloride, 1172  
 Sodium acrylate, reaction with phosphorous oxychloride, 1074  
 Sodium adipate, reaction with  $\alpha$ -monochlorohydrin, 668  
 Sodium alcoholate, catalyst, phenol-formaldehyde condensation, 354  
 Sodium aluminate, catalyst, cresol condensation, 354  
 Sodium aluminate, resin purification with, 337  
 Sodium amalgam, as catalyst, 181, 182, 193  
 —, as reducing agent, 277, 375  
 Sodium anilide, reaction with trichloroethylene, 1138  
 Sodium aniline-ethane- $\alpha$ -sulphonate, condensation with crotonaldehyde, 708  
 Sodium anilinemethane- $\omega$ -sulphonate, condensation with formaldehyde, 708  
 Sodium benzenesulphonate, in phenol-aldehyde resins, 372  
 Sodium berylate, catalyst, acetaldol formation, 498  
 Sodium bicarbonate, catalyst, phenol-aldehyde reaction, 420  
 —, —, urea-paraformaldehyde condensation, 616  
 Sodium bisulphate, catalyst, dioxane preparation, 993  
 —, —, hydrocarbon-aldehyde resin, 265  
 —, —, phenol-glycerol resin, 393  
 —, in alkylid resins, 911  
 —, in paper-impregnation, 1328  
 —, phenol purification, 336  
 —, reaction with phenols, 422  
 Sodium bisulphite, as reducing agent, 180, 181  
 —, glyceride oils modified with, 1237, 1238  
 —, in purification of resins, 1135  
 Sodium borate, in phenol-aldehyde resins, 324, 437  
 —, ketone-aldehyde condensation, 559  
 —, suppression of gelation, methylolureas, 597  
 Sodium bromide, catalyst, phenol-formaldehyde reaction, 357  
 Sodium bromoethanesulphonate, reaction with abietic acid, 906  
 Sodium-butadiene rubber, treatment of, 195, 196

- Sodium butyl glycerol phthalate, in cellulose esters, 952, 953
- Sodium butylnaphthalenesulphonate, uses of, 179, 193
- Sodium carbonate, action on wood, 753
- , in aldehyde-ketone condensation, 546, 559
- , in bromination of phenols, 1154
- , in chlororubber, 1111, 1125
- , in diene polymerization, 182
- , in furfural resins, 523, 529, 670
- , in phenol alcohol resins, 333
- , in phenol-aldehyde condensation, 281, 324, 343, 347, 349, 352-354, 369, 417, 429, 437-439, 673
- , in rosin purification, 770
- , in rubber latex, 181
- , in urea resins, 617, 623, 640, 670
- Sodium chloride, diluent for sodium catalyst, 182
- , in absorption tests, 1344
- , in acetylene polymerization, 147
- , in phenol-aldehyde reaction, 372, 424
- , in rosin esterification, 300
- , in rubber latex, 181
- , in urea-formaldehyde condensate, 616
- Sodium chloride solution, surface testing with, 406, 407
- Sodium 3-chloro-2-hydroxypropanesulphonate, reaction with abietic acid, 805
- Sodium chromate, resin purification with, 336
- Sodium citrate-citric acid, condensing agent, urea and formaldehyde, 589
- Sodium cresylate, catalyst, phenol-formaldehyde reaction, 352
- , reaction with benzoyl chloride, 1234
- Sodium cyanide, catalyst, phenol-formaldehyde reaction, 353, 357
- Sodium dibutylnaphthalenesulphonate, catalyst, 193
- Sodium dichromate, vat dyeing, 1057
- Sodium dihydrogen phosphate, catalyst, 635
- Sodium disulphide, reaction with dibromoanthracene, 1202
- Sodium ethoxide, catalyst, ketone condensation, 551, 557, 563
- , in lubricating oil, 1158
- , reaction with ethylidene dichloride, 1035
- , — rubber tetrabromide, 1114
- , — titanium tetrachloride, 1239
- Sodium ethyl, catalyst, diene polymerization, 182
- Sodium ethyl sulphate, catalyst, urea resins, 618, 621
- Sodium fluosilicate, in cresolsulphonic acid-formaldehyde resin, 421
- Sodium formate, catalyst, cresol condensation, 354
- , —, phenol-sulphur reaction, 1191
- Sodium fusion, resins, 1258
- Sodium glycerate, in phenol-aldehyde resins, 429
- Sodium hydracrylate, preparation of, 1070
- Sodium hydride, in diene polymerization, 182
- Sodium hydro-bisulphite, reducing agent, 180, 181
- Sodium hydrogen phosphate, in latex coagulation, 181
- Sodium hydrogen sulphate, in urea resins, 621, 654
- Sodium hydroxide, action on acetaldehyde, 493, 1082
- , — Aroclors, 1146
- , — chlorinated oils, 1220

 —, surface resistivity, varnishes, 1374, 1375  
 —, time of curing, varnishes, 1362, 1363  
 —, drying, varnishes, 1364, 1365  
 —, volatile material, 1344  
 —, water absorption, varnishes, 1375-1377  
 Tetra-acetylpropane, reaction with thallium ethoxide, 1242  
 Tetra-amino-ditolyl-furyl-methane sulphate, condensation of furfural and m-tolylene-diamine sulphate, 519  
 Tetra-amylens, from trimethylethylene, 165  
 Tetra-benzoyl-ethylene, condensation, 556  
 Tetra-benzylsilicane, formation, 1238  
 Tetra-bromosuccinic acid, formation, 858  
 Tetra-chlorobutane, preparation of dichlorobutadiene from, 170  
 $\alpha,\beta,\beta,\beta$ -Tetra-chlorodiethyl ether,  $\beta,\beta$ -dichlorovinyl ether from, 1010  
 Tetra-chloroethane, softening agent, phenol-aldehyde resins, 423  
 —, solvent, 1137  
 Tetra-chloroethylene, 1140  
 —, reaction with formaldehyde, 516  
 Tetra-chloronaphthalene, retarder, alkyl resins, 881  
 —, soldering flux, 1154  
 Tetra-chlorophenol, softening agent, phenol-aldehyde resins, 423  
 Tetra-cyclic structure, urea resin, 581  
 Tetra-decadiene, bromination, 1156  
 Tetra-ethylammonium iodide, electrolysis, 731  
 Tetra-ethylammonium trichloride, catalyst, metaldehyde from acetaldehyde, 489  
 $\alpha,\alpha'$ -Tetra-ethyldiaminoadipic acid, polymerization, 731  
 Tetra-ethyl lead, catalyst, polymerization, vinyl chloride, 1040  
 Tetra-ethylene glycol, condensation with citric acid, 891  
 —, preparation, 898  
 Tetra-glycerol hexa-acetate, preparation, 995  
 $\Delta^6$ -Tetra-hydrobenzaldehyde, preparation, 831  
 $\Delta^6$ -Tetra-hydrobenzaldehyde-3,5-endomethylene, formation, 834, 835  
 $\Delta^5$ -Tetra-hydrobenzaldehyde-6-methyl, preparation, 832  
 $\Delta^5$ -Tetra-hydrobenzaldehyde-3-phenyl, 831  
 Tetra-hydrobenzene oxide, reaction with pentaerythritol, 896  
 1,2,3,4-Tetra-hydro-6- $\omega$ -chloromethylnaphthalene, 1133  
 Tetra-hydrofuran, from tetramethylene carbonate, 870  
 Tetra-hydrofurfural, reaction with phenylhydrazine, 819  
 Tetra-hydrofurfuryl alcohol, solvent, polyvinyl chloride, 1038  
 Tetra-hydrofurfuryl glyceryl ether, condensation with phthalic anhydride, 900  
 Tetra-hydro-methyl-benzalacetone, formation, 832  
 Tetra-hydronaphthalene, action of air on, 270  
 —, condensation with butadiene, 194  
 —, — para-formaldehyde, 265  
 —, — sulphonated chloroacetone-phenol resin, 421  
 —, fluxing agent, 337  
 —, halogenated, 1138, 1137  
 —, resins from, 270, 510  
 —, solvent, amine-aldehyde condensation products, 700  
 —, sulphonation, 371  
 Tetra-hydronaphthalene sulphonamide, reaction with formaldehyde, 712, 713  
 Tetra-hydronaphthol, reaction with abietic acid, 800  
 ar-Tetra-hydronaphthol alkyl ethers, preparation and condensation, 371  
 Tetra-hydronaphthonic acids, substitute for shellolic acid, 1006  
 $\Delta^{2,6}$ -Tetra-hydro-1,4-naphthoquinone, preparation, 832  
 Tetra-hydro-normethylmorphinethine, resinous properties, 745  
 Tetra-hydro-phenanthrene, from phenanthrene, 268  
 Tetra-hydro-phthalic acid, 884  
 $\Delta^4$ -Tetra-hydro-o-phthalic anhydride, reaction with glycerol, 832  
 $\Delta^4$ -Tetra-hydro-phthalic anhydride-3,6-endomethylene, preparation, 835  
 Tetra-hydro-quinazoline, preparation, 834  
 Tetra-hydrostyrene, solvent for butadiene polymerization, 183  
 Tetra-hydroxystearic acid, use in alkyl resins, 910  
 5,6,5',6'-Tetra-hydroxy-3,3',3'-tetramethylbis-1,1'-spirohydrindene, preparation, 287  
 Tetra-indene, from indene, 100  
 Tetra-ldan, from acetal-dol, 498  
 Tetra-ldene, reaction with phenol, 330  
 Tetra-lin, combination with polyvinyl chloride, 1035  
 —, drying resin from, 269  
 —, solvent for furfural resin, 530  
 Tetramers, acetylene polymerization, 147, 148  
 2,3,6,7-Tetramethyl anthraquinone, formation, 833  
 2,3,6,7-Tetramethyl anthrone, formation, 833  
 1,2,4,5-Tetramethylbenzene, 724  
 1,2,3,4-Tetramethylbutadiene, 169  
 p,p'-Tetramethyldiaminodiphenylmethane, formaldehyde and dimethylaniline, 687  
 Tetramethylene carbonate, decomposition, 870  
 Tetramethylene sulphide, polymerization, 1170  
 2,3,6,7-Tetramethyl- $\Delta^{2,6}$ -hexahydro-9,10-anthrahydroquinone, structure, 833  
 2,3,6,7-Tetramethyl- $\Delta^{2,6}$ -octahydroanthraquinone, isomerization, 833  
 2,2,6,6-Tetramethylol-cyclohexanol, alkyl resins from, 904  
 Tetramethylol-cyclohexanol, from cyclohexanone and formaldehyde, 559  
 Tetramethyl quinolinine-1,2,3,4-tetracarboxylate, formation, 850, 851  
 Tetramethylthiuram disulphide, softener, olefin-polysulphide rubber, 1174  
 Tetramethylthiuram monosulphide, action on rubber, 1102  
 Tetra-m-nitrotetraphenylsilicane, formation, 1238  
 Tetraphenoxyl-dihydroxy-rubber, 1114  
 1,2,3,4-Tetraphenyl benzene, formation, 842  
 1,1,2,3-Tetraphenyl-1-butene, from asym-diphenylethylene, 269  
 3,3,4,4-Tetraphenylcyclobutane-1,3-dione, from benzylic acid and sodium carbonate, 558  
 Tetraphenylcyclopentadienone, reaction with maleic anhydride, 842  
 3,4,5,6-Tetraphenyl-1,3-dihydrophthalic anhydride, formation, 842  
 Tetraphenyldimethyl ether, treated with hydrochloric acid, 1188  
 2,2,3,6-Tetraphenylhydrindone, 842, 843  
 Tetraphenylsilicane, nitration, 1238  
 Tetraphenylthiophene, formation, 1197  
 Tetroxymethylene, from formaldehyde, 513  
 Textile dressing, styrene-maleic anhydride resin, 244

- Textile fabrics, coated with resin globules, 1247  
 —, use of polystyrene solutions, 245  
 Textile finishes, carbohydrates, 753  
 Textile impregnant, sulphurized stearin pitch, 1203  
 Textile materials, impregnation with alkyl resin emulsions, 947  
 Textile oils, from tall oil, 756  
 Textiles, affinity for dyes, effect of resins, 642  
 —, impregnation, urea resins, 660  
 —, treatment with Aroclor resins, 1147  
 —, use of alkyl resins, 910, 911  
 —, — chlororubber, 1127  
 —, — phenol and urea resins, 639  
 Textile sheets, use, laminated insulation, 1249  
 Textile webbing, impregnated with cumarone resin, 136  
 Textured floor covering, preparation, 934  
 Thallium, stabilizer, plastic sulphur, 1164  
 Thallium compounds, resinous, 1235  
 Thallium ethoxide, reaction with tetra-acetylpropane, 1242  
 Thallium oxide, stabilizer, plastic sulphur, 1164  
 Thallium phenolates, reaction with aldehydes, 438  
 Thallium trichloride, catalyst, 1131  
 Therapeutic agents, from copal, 810  
 —, from ethylene oxide, 993  
 Therapeutic properties, modified cumarone resins, 118  
 Thermal conductivity, sheet material, 1354  
 Thermal decomposition, acetylene and methane, 162  
 —, divinylacetylene, 152  
 Thermal economy, urea manufacture, 568  
 Thermal-hardening properties,  $\beta$ -eleostearin, 1216  
 Thermal insulation, modified phenol-aldehyde resin, 441  
 Thermal plasticity, 32  
 Thermal resistance, cumarone resins, 115  
 Thermal synthesis, biphenyl, 1143  
 Thermolyzed tung oil, 1217  
 Thermoplasticity of Aroclor resins, 1150  
 Thermoplastic materials, constituents, 826  
 —, decorating, 1333

 —, flow, 1330  
 —, from rubber, 1098, 1102  
 —, heat marks, 1329  
 Thermoplastic molding, methods of, 1314-1316  
 Thermoplastic moldings, 1265, 1266  
 Thermoplastic resins, from methyl methacrylate, 1081  
 —, injection molding, 1324  
 Thermopolymerization, indene, 100  
 Thermoprene, preparation and properties, 1099, 1100  
 Thermoreactive resins, 1266  
 Thermorigid resins, from phenol alcohols, 332  
 Thermosetting materials, definition, 14  
 —, flow, 1329  
 —, heat marks, 1329  
 Thermosetting resins, urea resins, 564, 565  
 —, uses, 11, 1265  
 Thermostatic control in dielectric tests, 1347  
 Thialdines, preparation, 1181  
 Thianthrene, formation, 1201  
 Thickening, wash-oil, 122  
 Thickening agents, for hydrocarbon oils, 1137  
 —, from alkylated polyvinyl alcohol, 1067  
 —, polyvinyl ethers, 1060  
 Thickness, films, effect on water absorption, 1377  
 —, laminated material, variation of dielectric, 1346  
 —, test specimens, 1342  
 Thioacetaldehyde, condensation with phenol, 378  
 Thioacid derivatives, resinification, 1181  
 Thioaldehydes, condensation with urea, 682, 683, 1183  
 Thioaldehydes, polymerisation, 1180  
 Thioamides, condensation with nitriles, 658  
 —, — sulphur chloride, 1193  
 —, use with resins, 644  
 Thioaniline, formation, 1194  
 —, from aniline and sulphur, 704  
 Thiobenzanilide, formation, 1197  
 Thiobenzophenone, autooxidation, 1180  
 $\alpha,\beta$ -Thiobutane, 1169  
 Thiocarbamide, combination with metal salts, 580  
 Thiocarbamilide, diphenylisothiohydantoin from, 575  
 —, formation, 1197  
 —, from aniline and carbon disulphide, 652  
 —, glyceride oils modified with, 1227  
 —, plasticizer, 447  
 —, reaction with chloroacetic acid, 575  
 Thiocresols, reaction with aldehydes, 377  
 Thio-p-cresol, reaction with divinylacetylene, 152  
 Thiocyanodiamidine, preparation, 681  
 Thiocyanometry of tung oil, 861  
 Thiodicyanodiamidine, reaction with formaldehyde, 681  
 Thiodiglycolic acid, 894  
 —, reaction with cellulose, 904  
 —, use in alkyl resins, 883  
 Thiodilactylic acid, 894  
 Thioethers, thermal decomposition, 230  
 Thioformaldehyde, condensation with phenol, 378  
 —, — urea, 1182  
 —, polymerization, 1179  
 Thiofural, preparation and properties, 538  
 Thiofurfural, from reaction of furfural and ammonium sulphide, 536  
 Thioglycerol resins, 1177  
 Thioglycerols, preparation and properties, 1176, 1177  
 Thioglycolic acid, action on rubber, 1104  
 Thioketones, polymerization, 1180  
 Thiokol, use with chlororubber, 1128  
 Thiokol A, olefin-polysulphide product, 1174  
 —, preparation and properties, 1175, 1176  
 Thiolactic acid, reaction with cellulose, 904  
 Thionite, preparation, 1189  
 Thiols, sulphonic acids from, 1178  
 Thionylaniline, reaction with malonic acid, 1195  
 Thionyl chloride, action on methyl lupinate, 745  
 —, — rubber, 1101  
 —, — triphenylmagnesium bromide, 1142  
 —, catalyst, condensation 3,3,4,4-tetraphenylcyclobutane-1,2-dione, 553  
 —, — phenol-acetaldehyde reaction, 381

 Xylene methyl sulphonamide, plasticizer for acetyl cellulose, 719, 720  
 Xylene-paraformaldehyde-tung oil reaction, triethanolamine, catalyst, 403  
 Xylenes, condensation with isoprene, 193, 194  
 Xylenesulphonamide-aldehyde resins, lacquers from, 717, 718  
 Xylenol, chlorination of, 1154  
 —, 2,3-, 2,5-, 2,4-, sym-, position of attack, 292  
 p-Xylenol, isolation of, from coal tar, 361  
 sym-Xylenol, electrolytic oxidation, 272, 371  
 —, methyl and ethyl ethers of, reaction with formaldehyde, 407  
 —, phenol and m-cresol, similarity in resin formation, 292  
 —, velocity of condensation with formaldehyde, 366  
 —, m-xylohydroquinol from, 371  
 Xylenol-acrolein resin, 392  
 Xylenol-aldehyde-alkyl resin compositions, formation of, 938  
 sym-Xylenol ether, condensation, with formaldehyde, 371  
 Xylenol-formaldehyde resin, hardening of, 369, 370  
 —, laminated sheets from, 370  
 —, molding, 370  
 —, preparation of, 938  
 —, removal of water, 370  
 —, solution in drying oils, 370  
 —, varnishes from, 370  
 —, x-ray pattern of, 83, 84  
 Xylenol resins, use of, 413  
 Xylenols, action of moist air on, 270  
 —, catalysts for oxidation of, 270  
 —, condensation, with o-benzoylbenzoic acid, 376  
 —, — formaldehyde and its polymers, 369, 370, 407, 408  
 —, — furfural, 370  
 —, — furfural and formaldehyde, 530  
 —, 2,4- and 2,6-diphenolmethane from, 292  
 —, dixylenols from, 272  
 —, in coal, 261, 366, 369  
 —, mono-alcohols from, 293  
 —, physical properties of, 366  
 —, present in cresylic acid, 359  
 —, resins from, 270  
 —, solubility of resins from, 270, 271  
 Xylidine, condensation with alchol, 790  
 —, — crotonaldehyde, 700, 701  
 —, — formaldehyde, 700, 701

asym-m-Xylidine, reactions of, 732  
 Xylidine-furfural resin, 534  
 —, light-sensitive material from, 539  
 Xylidines, condensation with acetaldehyde, 703  
 —, softening agents, phenol-aldehyde resins, 424  
 —, use of, 347  
 m-Xylohydroquinol, from sym-xylenol, 371  
 Xylol, solvent, for Resyls, 973  
 m-Xyloquinone from m-xytol, 272  
 Xylose-aniline condensation, 763  
 Xylol chloride, reaction with naphthalene, 1131  
 —, — rosin, 799  
 p-Xylylene dibromide, reaction with sodium, 1141  
 Xylylene dichloride, condensation with hydrocarbons, 1134  
 —, resins from, 1129  
 Xylylene glycol, monoalkyl ether of, 1131  
 m-Xylol ethyl ether, use of in cumarone polymerization, 117  
 Xylyloxy-fatty acids, reaction with formaldehyde, 375  
 1-p-Xylol-1,2,3-triazole-4,5-dicarboxylic acid, dihydrazide, resins from, 736

## Y

Yacca gum, with polyvinyl resins, 1067  
 Yeast, aldehydase in, 494  
 Yeast-gum derivatives, 763  
 Yeast protein, modifier, phenol-formaldehyde resin, 416  
 Yellowing, cumarone resin varnishes, 126, 127  
 —, oilcloth, 137  
 —, resins and plasticizers, 958  
 —, synthetic resin coatings, prevention of, 1378  
 —, varnishes, prevention of, 1378  
 —, white enamels, 819  
 Yellowing resistance tests, for varnishes, 1377  
 Yield value, nature of, 34  
 Yoshino paper, 962, 1246  
 Young's modulus of elasticity, 1341

## Z

Zanzibar, urea resin lacquers with, 632  
 Zinc, action on rosin, 769  
 —, activated with mercury, 1074  
 —, catalyst, 1129, 1130  
 —, —, acetone-vinyl bromide reaction, 1253  
 —, —, dechlorination, 220  
 —, —, esterification of copal, 809  
 —, —, etherification of polyvinyl alcohol, 1067  
 —, —, ethyl acrylate from ethyl  $\alpha,\beta$ -dibromopropionate, 1074  
 —, —, hardening, alkyl resins, 981  
 —, —, methyl acrylate preparation, 1074  
 —, —, phenol-alkyl halide reactions, 1133  
 —, —, polymerization of furfural, 521  
 —, —, rosin esterification, 794, 795, 796, 799, 800  
 —, —, urea-guanidine-formaldehyde reaction, 682  
 —, plasticity of, 31, 32  
 —, reaction with bromoacetyl bromide, 552  
 —, — urea-alcohol resins, 664  
 —, with cobalt as drier in baking enamels, 976  
 Zinc-aluminum foil, catalyst, polymerization, vinyl bromide, 1037  
 Zinc acetate, catalyst, phenol-aldehyde condensation, 369  
 —, —, reaction of acetylene and organic acids, 1018  
 Zinc alkyls, vulcanization of rubber by, 1103  
 Zinc  $\alpha$ -aminoselenophenolate, condensation with o-nitrobenzoyl chloride, 727  
 Zinc benzenesulphonate, use, with phenol-aldehyde resins, 372  
 Zinc benzoate, catalyst, reaction, acetylene and organic acids, 1018  
 Zinc bromide, action on rubber, 1103  
 Zinc butyl phthalate, preparation of, 952  
 Zinc butyl xanthate, reaction with sulphur, 1103  
 Zinc butyrate, catalyst, in the conversion of  $\alpha$ -into  $\mu$ -polychloroprene, 157  
 Zinc carbonate, catalyst, rosin esterification, 795  
 —, —, urea-formaldehyde, 551, 616  
 —, modifier, phenol-aldehyde resins, 428  
 Zinc chlorate, as ansovo-acid, 194

- Zinc chloride, action on heptene oxides, 1254  
 —, — hydrogen-carbon monoxide product, 1255  
 —, — indene, 102  
 —, — lubricating oils, 215  
 —, — olefins, 201  
 —, — turpentine, 781  
 —, — vinyl esters, 1032  
 —, — as ansovo-acid, 194  
 —, — catalyst, aldehyde-amine, 708, 707  
 —, — aldehyde-dihydroxybenzophenone, 373  
 —, — alkylated phenols, 411  
 —, — alkylation of phenol-aldehyde resins, 421  
 —, — aralkyl halide-hydrocarbon, 1132  
 —, — benzal chloride resins, 1134  
 —, — benzene-formaldehyde, 265  
 —, — benzoyl cyanide-resorcinol, 378, 737  
 —, — conversion of  $\alpha$ -into  $\mu$ -polychloroprene, 157  
 —, — cresol-alkyl alcohol, 434  
 —, — dicyanodiamide-formaldehyde, 680  
 —, — dimethylamine and  $\beta$ -ethoxy-acrolein-acetal, 690  
 —, — esterification of shellac, 813  
 —, — ethylene glycol and glutaric acid, 898  
 —, — formaldehyde-alkyl salicylate, 374  
 —, — furfural-aniline, 535  
 —, — furfural-phenol, 527  
 —, — hardening, furfural-aniline resin, 533  
 —, — — phenol-acetaldehyde resins, 381  
 —, — hydrocarbon-aldehyde resins, 265  
 —, — hydroxytoluic acid-acetaldehyde, 374  
 —, —  $\beta$ -naphthol ethyl ether-formaldehyde, 407  
 —, — phenol-acrolein, 391  
 —, — phenol-formaldehyde, 352, 356  
 —, — phenol-lignin, 747  
 —, — phenylhydrazine and benzaldehyde, 735  
 —, — polyglycerol formation, 995  
 —, — polymerization, 117, 166, 183, 222, 227, 228, 553, 990, 1001  
 —, — preparation of polyvinyl acetals, 1060  
 —, — reaction of acetylene and hydrogen chloride, 1036  
 —, — — allyl esters with phenols, 394  
 —, — — benzaldehyde and hydrogen persulphide, 1182  
 —, — — p-hydroxybenzophenone, 555  
 —, — — phenol and vinyl esters, 1031  
 —, — resin esters from benzyl chloride, 799  
 —, — resins from malt, 762  
 —, — resorcinol-diphenic anhydride, 391, 732  
 —, — rosin-alkyl halide, 1132  
 —, — rosin esterification, 795, 800  
 —, — styrene from chloroethylbenzene, 253  
 —, — sulphonamide-aldehyde resins, 714, 715  
 —, — synthesis of cumarone, 93  
 —, — toluidine reaction with tung oil, 1219  
 —, — two-stage wet process, for phenol-aldehyde resins, 317  
 —, — urea-formaldehyde, 635  
 —, — dehydrating agent, 405, 410, 550  
 —, — hardening catalyst, 357, 980, 1029  
 —, — preservative, for test panels 1368  
 —, — production of rosin oil, 779  
 —, — reaction with acetone, 541  
 —, — borneol, 725  
 —, — oleic acid in acetic acid 1222  
 —, — tung oil, 1218, 1219  
 —, — tung oil polymerised with, 1219  
 —, — use, fireproofing fibers, 416  
 —, — — in alkyd resins, 909, 941  
 —, — with phenol-aldehyde resins, 372  
 Zinc chromate, catalyst, for hydrogenation of esters, 907  
 Zinc-chromate-synthetic resin primer, for airplane coatings, 1378  
 Zinc chromite, catalyst in ethanol-acetaldehyde condensation, 495  
 Zinc-copper couple, action on benzyl halides, 1130  
 —, — hydrogenation of furfural, 519  
 Zinc dust, action on benzal chloride, 1134  
 —, — benzyl chloride, 1130, 1131  
 —, — catalyst, 355  
 —, — benzyl chloride and phenol reaction, 295  
 —, — condensation of urea and formaldehyde, 644  
 —, — esterification of tall oil, 756  
 —, — phenol-formaldehyde reaction, 281, 343  
 —, — preparation of phenol-sulphur resins, 1185  
 Zinc foil-ion, catalyst, polymerisation, vinyl bromide, 1037  
 Zinc formate, buffering agent, urea-formaldehyde condensation, 612  
 Zinc hydroxide, modifier, phenol-aldehyde resins, 438  
 —, — resin purification with, 337  
 Zucke reaction, 1129  
 Zinc meta-arsenite, preservative, for test panels, 1368  
 Zinc monoalkyl phthalic acid, preparation of, 950  
 Zinc naphthenates, 206, 207, 967  
 Zinc nitrate, catalyst, acetylene and aniline, 704  
 Zinc oleate, modifier, 400  
 Zinc oxide, action in synthetic rubber, 196  
 —, — action on benzal chloride, 1134  
 —, — chloroprene rubber, 157  
 —, — solidification temperature, alkyd resins, 881  
 —, — wood tar, 752  
 —, — antacid for phenol-sulphur resins, 1185  
 —, — catalyst, acetaldol formation, 498  
 —, — dechlorination, 220  
 —, — phenol-formaldehyde reaction, 281, 343  
 —, — polymerization of formaldehyde, 394, 516  
 —, — resinification, triphenyl phosphate, 432  
 —, — rosin esterification, 795  
 —, — separation of styrene, 254  
 —, — solidification of alkyd resins, 960, 981  
 —, — urea and formaldehyde, 616  
 —, — filler, chlororubber cement, 1126  
 —, — olefin-polysulphide rubber, 1174  
 —, — phenol-aldehyde resins, 317, 318  
 —, — in gloss-white enamel, 967  
 —, — in hardened rosin, 772  
 —, — in production of low acid number alkyd resins, 977  
 —, — in shellac compositions, 778  
 —, — modifier, phenol-aldehyde resins, 437, 438  
 —, — polymerization of linseed oil-tung oil mixture, 1227, 1228  
 —, — reaction with fatty oils, 1213  
 —, — resin purification with, 337  
 —, — use, in alkyd resins, 917  
 —, — in insulating materials, 722  
 —, — vulcanization of synthetic rubber, 195, 197, 198, 200  
 —, — with chlorinated rubber, 1107, 1108, 1111, 1120  
 —, — with copal esters, 817, 819  
 —, — with eugenol-formaldehyde resin, 375  
 —, — with Rexyls, 973  
 Zinc resinate as scorch-retarder for rubber, 985  
 —, — catalyst, rosin esterification, 799  
 —, — modifier, 400  
 —, — use in alkyd resins, 932  
 Zinc salicylate, use, with phenol-aldehyde resins, 372  
 Zinc salts, catalysts, phenol-acetylene resins, 385  
 —, — rosin esterification, 794, 795  
 —, — neutralising agents, 344  
 —, — of methacrylic acid, polymerization of, 1080  
 —, — with resins, for treatment of textiles, 452, 640  
 Zinc stearate, dusting powder, 791  
 Zinc sealer, 970  
 —, — mold lubricant, 620, 983, 1237, 1238  
 Zinc soaps, modifiers, phenol-aldehyde resins, 438  
 Zinc sulphide, use of, 433  
 Zirconium chloride, catalyst, 1130  
 —, — phenol-formaldehyde reaction, 356  
 Zirconium oxide, plastics from, 82  
 Zirconium salts, with resins, for treatment of textiles, 452, 640
